Bearskin Project – 2008 Prospecting Sample Locations (scale: 1:5000)

INTRODUCTION:

From May to October 2008, a systematic prospecting program was completed over the Bearskin Lake claim group situated in Walters and Irwin Townships in the Thunder Bay Mining Division. The purpose of the program was to examine previously known gold showings on the property and to prospect for any new mineralization. The 22 unit claim group is held under option by Kodiak Exploration Limited (Kodiak). The work program being reported on was carried out by Kodiak contract personnel.

The property is situated approximately seven kilometres east southeast of the shear hosted Brookbank gold deposit. This deposit reports a resource of 3.2 million tonnes at 6.65 grams per tonne (gpt) gold.

LOCATION AND ACCESS.

The Bearskin Lake claim group is situated in Walters and to a small extent, Irwin Townships approximately 220 kilometres by Highways 11/17 and 11 and Provincial Road 801, northeast of Thunder Bay, the nearest major centre (Figure 1). Beardmore, the closest community, is situated on Highway 11 approximately 16 kilometres to the southwest.

Provincial Road 801 transects the eastern portion of the claim group at kilometre 7. An abandoned logging road heading westerly across the central portion of the claim group can be accessed from Provincial Road 801.

PHYSIOGRAPHY

The topography of the property consists of broad undulating hills with the areas underlain by metavolcanic units having a higher relief than the areas underlain by the softer metasedimentary units. Relief on the property is in the order of 45 metres. The area underlain by the metasediments generally has only 10-15 metres of relief.

Vegetation comprised of black spruce, dominates the low lying areas with alder and cedar in the muskeg areas. The higher areas are characterized by mixed forest comprised of poplar and spruce with lesser birch.

According to the quaternary geology map (Kristjansson, et al, 1990), the northern 2/3 of the property has a thin, discontinuous till cover. This area corresponds closely with that portion of the claim group underlain by the more resistant, predominantly mafic volcanics. The southern third of the property, which is underlain by metasediments, has a thick mantling of sand and gravel.

PREVIOUS WORK

According to Mackasey (1976), geologic mapping in the area was conducted sporadically from 1869 to the mid-1960's. From this point to the mid to late 1970's, a comprehensive mapping program was completed in the Beardmore-Jellicoe area. A brief chronology of these activities follows.

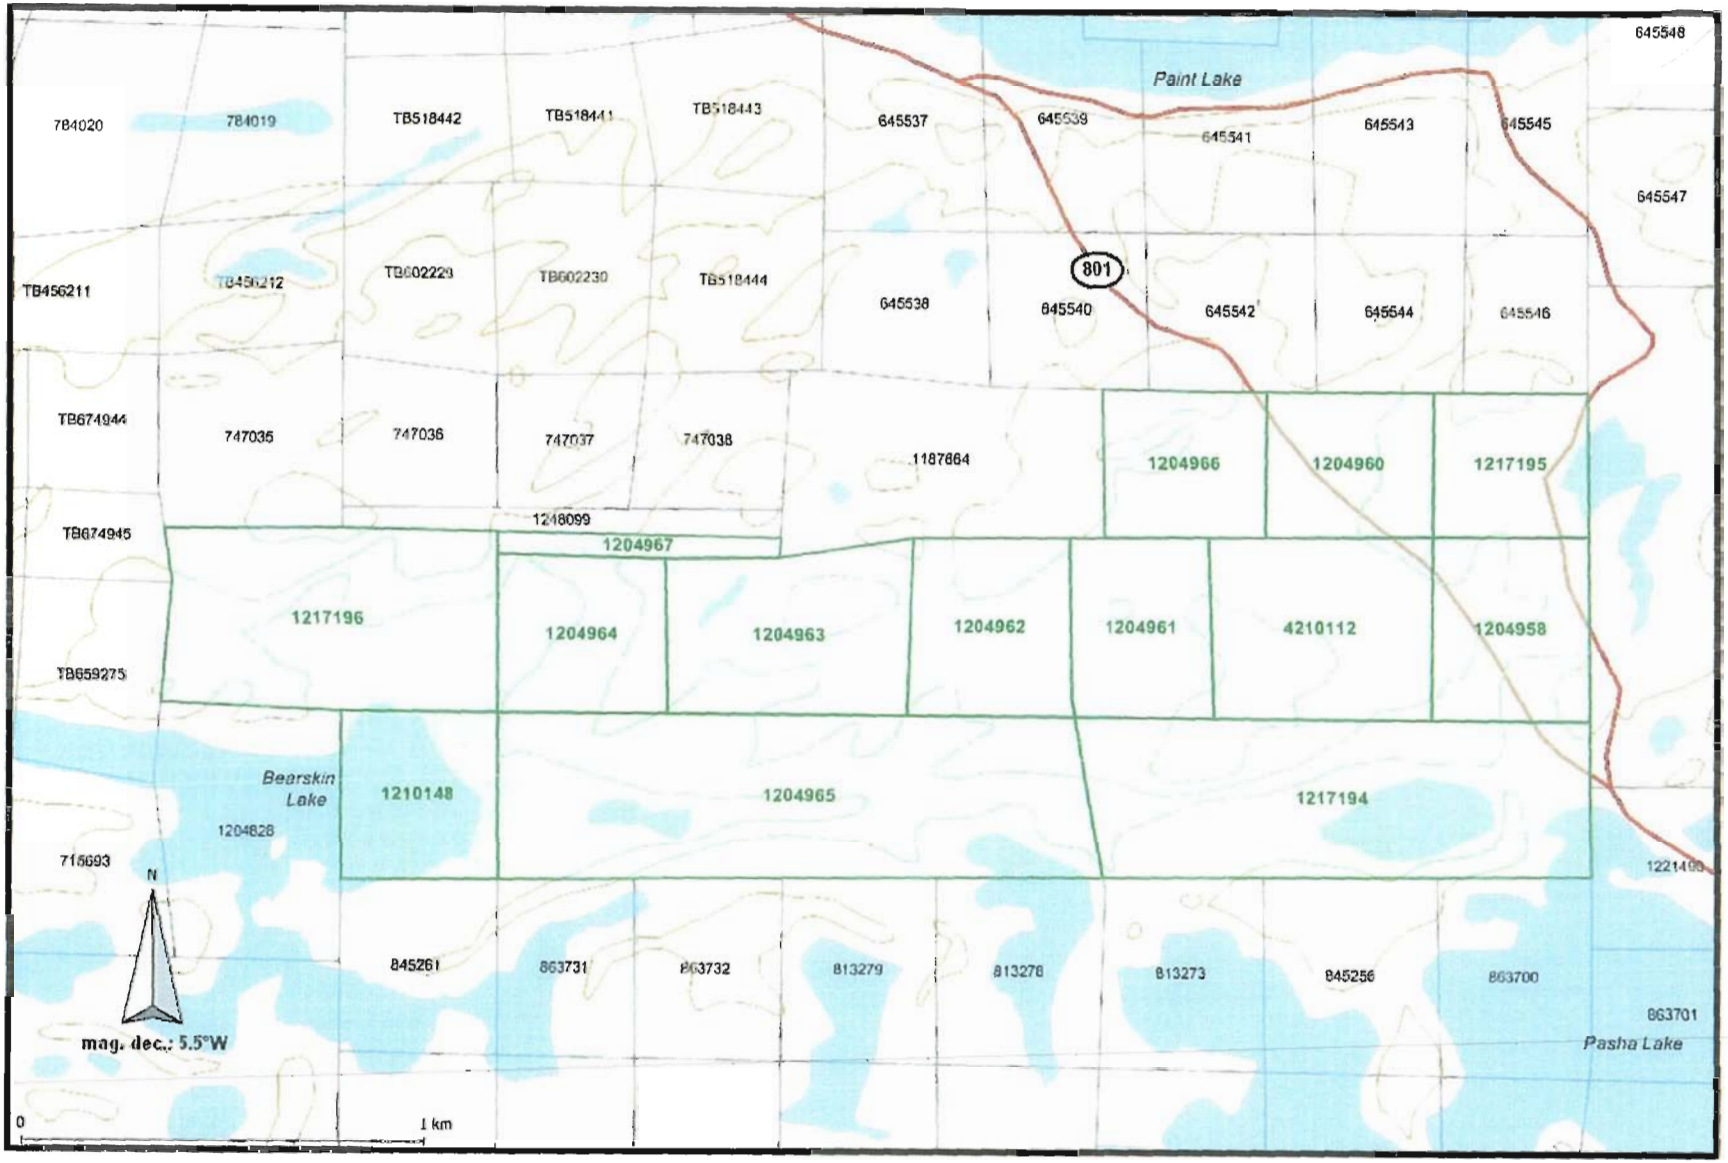

Figure 2: The Bearskin Lake claim group, Thunder Bay Mining District.

From the first recorded geological work in 1869 up to 1910, geologic investigations were carried out by Bell and McKellar (1869), McInnes (1894), Dowling (1898), Parks (1901), Wilson (1910). The iron deposits of the region were investigated in the early 1900's by Coleman (1907) and Moore (1907), and Burrows in 1916 on behalf of the Ontario government, examined the geology along the railway from Beardmore to Jellicoe. Mapping in the Windigokan Lake area by the Geological Survey of Canada was carried out by Tanton in 1917 and Langford in 1927. The work by Burrows and Tanton was confined to the geology along the railway between Nipigon and Longlac.

In 1936, Bruce and Liard published a comprehensive report on the geology and mineral deposits of the area for the Ontario Department of Mines.

In the 1950's, Horwood and Pye (1951), Peach (1951) and Pye (1951) carried out geological investigations in the area, and a compilation map by Pye et al, covering the Tashota-Geraldton area was published by the Ontario Department of Mines in 1966.

Geologic mapping of the Beardmore-Jellicoe area by Mackasey for the Ontario Department of Mines began in 1967 and resulted in a number of reports being published from 1969 to 1975. Later in 1983, mapping of McComber and Vincent Townships was carried out by Carter and the resulting preliminary maps and report were published as an open file report Carter (1987).

The first gold in the area was discovered near Beardmore in 1925 (Mackasey, 1975). The subsequent gold exploration efforts in the area resulted limited production from the Sturgeon River mine from 1937 to 1942, and an exploratory shaft sunk on the Soloman's Pillars property. Later exploration activities in the area remained focused on gold as well as iron and base metals.

Exploration assessment filings that cover all or part of the current claim group are itemized below.

1944: Lake Bearskin Mining Syndicate carried out a program of mapping, trenching and diamond drilling. (42E12NE0151)

1985: Wescap Energy Corporation flew a regional Aerodat helicopter VLF, electromagnetic and magnetic survey. The current claim group was within the survey area. (42E12NE0111)

1987: Coulson Exploration Inc. completed a geological survey of the Pasha Lake area, the area covered by the east portion of the current claim group. (42E12NE0102)

1987: Coulson Exploration Inc. completed a geological survey of their Bearskin Lake property, the area covered by the west portion of the current claim group. (42E12NE0103)

1998: Cox, Holt and Nelson, three local prospectors, on 14 claims 12 of the claims comprise the current claim group carried out targeted prospecting, limited trenching and stripping focusing on the main break on the property, the shear along the volcanic-sedimentary contact. A grid was cut and reconnaissance VLF and magnetometer surveys completed. (42E12NE2001)

1999: Cox, Holt and Nelson, tnree local prospectors, carried out targeted prospecting, limited trenching and stripping, and sampling focusing on a silicified zone on claim 1204964. (42E12NE2009)

2000: St. Anthony Resources Inc. completed magnetometer and VLF EM surveys over the current claim group which was under option from Cox, Holt and Nelson (42E12NE2010).

Regional Geological Setting

The Beardmore-Geraldton Belt (BGB) is situated along the south margin of the eastern portion of the Wabigoon subprovince (Lafrance et al, 2004) within the Archean Superior province (Figure 3).

The region in which the claim group is situated encompasses the north margin of the Beardmore-Geraldton Belt (BGB)

The BGB belt is bounded by the Quetico Subprovince on the south and the Onaman-Tashota Belt to the north.

The BGB is on average, 30 kilometres wide and extends east from the Proterozoic Lake Nipigon Embayment to Longlac, a length of approximately 125 kilometres. The belt is characterized by alternating panels of mafic volcanic and clastic sedimentary units with each panel being bounded by dextral shears. The age of the belt is 2.69-2.92 Ga. with the older volcanics at 2.72 Ga. and the overlying sediments deposited at2.69-2.70 Ga.

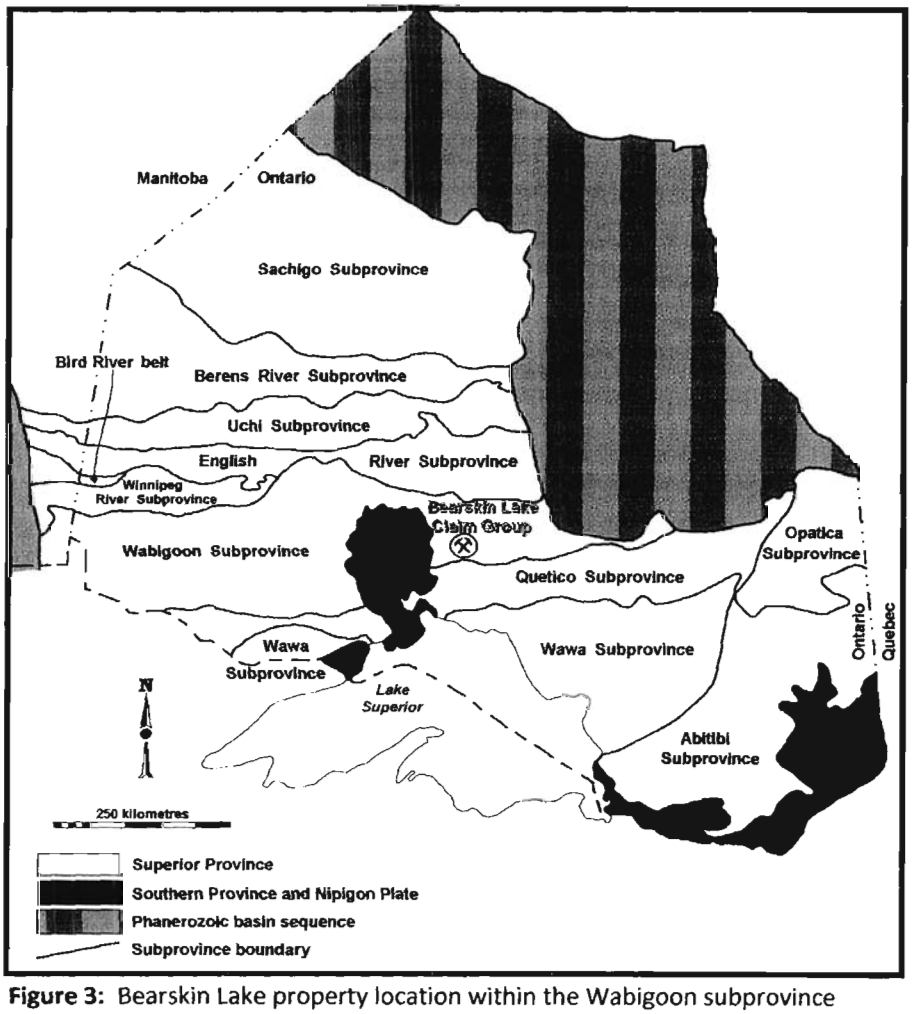

Figure 3: Bearskin Lake property location within the Wabigoon subprovince (modified after Card and Ciesielski, 1986).

The sedimentary sequence suggests Timiskaming type units, i.e., fluvial/alluvial depositional environment characterized by quick facies changes laterally and vertically. Polymict conglomerate is

the dominant sedimentary unit and is comprised of pebble to boulder sized clasts of variable compositions (granitic, felsic and mafic volcanic, jasper, black chert and quartz) in a feldspathic sandstone matrix indicative of a fluvial and/or alluvial depositional environment. The north, central and south sedimentary panels when taken together represent a shoreline to deeper water depositional environment (Lafrance et al, 2004).

The <1 kilometre thick north sedimentary panel is dominated by by the polymict conglomerate with minor sandstone . The south sedimentary panel, by contrast, is dominated by thick deposits of feldspathic sandstone with finely bedded siltstone and agrillite interlayers. Conglomerate within this latter panel occurs only as thin beds, and banded iron formation consisting of finely layered magnetite rich beds and jasper-hemitite beds are interlayered with fine grained sediments (argillite, siltstone and sandstone). Sedimentary features within this panel indicate a deep water turbiditic environment. The central sedimentary panel where conglomerate overlays a sequence of feldspathic sandstone, siltstone, argillite and minor iron formation, appears to be transitional between the north and south panels.

The south volcanic panel consists of massive and pillowed basalts and andesites of the MORB geochemical affinity with thin sedimentary and tuffaceous interlayers. Although well deformed in the well exposed Beardmore area, top indicators indicate younging to the north. The central panel units appear to have been deposited in a shallow water or sub-aerial environment as evidenced by the thicker and more extensive pyroclastic units and the large amygdules in the calc-alkaline andesitic and dacitic flows. Tops are unknown in this panel. Rare and trace element geochemistry suggests a depositional environment of an emergent volcanic arc above a subduction zone. Massive and amygdaloidal, pillowed, tholeiitic basalts and andesites dominate the north panel with the trace element geochemistry pointing towards either an immature arc or a back-arc environment. (Lafrance et al, 2004)

Intrusives within the belt consist of minor gabbro to diorite bodies and later quartz-feldspar porphyries stocks and sills, and the granodioritic Croll Lake Stock in the Geraldton-Longlac portion of the belt. Occasional Proterozoic diabase and related feldspar+quartz porphyry dikes cut the belt.

Metamorphism throughout the belt attained greenschist grade.

Structurally, the belt has been subjected to three events. The first event, D_1, is suggested by Lafrance et al (2004) to be the isoclinal folding resulting from thrusting. This thrusting would have resulted in the imbrications necessary to interleave the sedimentary and volcanic panels.

The second structural event (D_2) consisted of regional folding and shearing. These folds are most evident in the Beardmore and Geraldton portions of the belt. Both the folds and the dextral shearing parallel to the trend of the belt and overprint the D_1 folds. The tight to isoclinal folds are prominent features in the southern sedimentary panel in both the Beardmore and Geraldton areas. The northeast trending Jellicoe fault transects the BGB and displays a sinistral offset. The offset of this

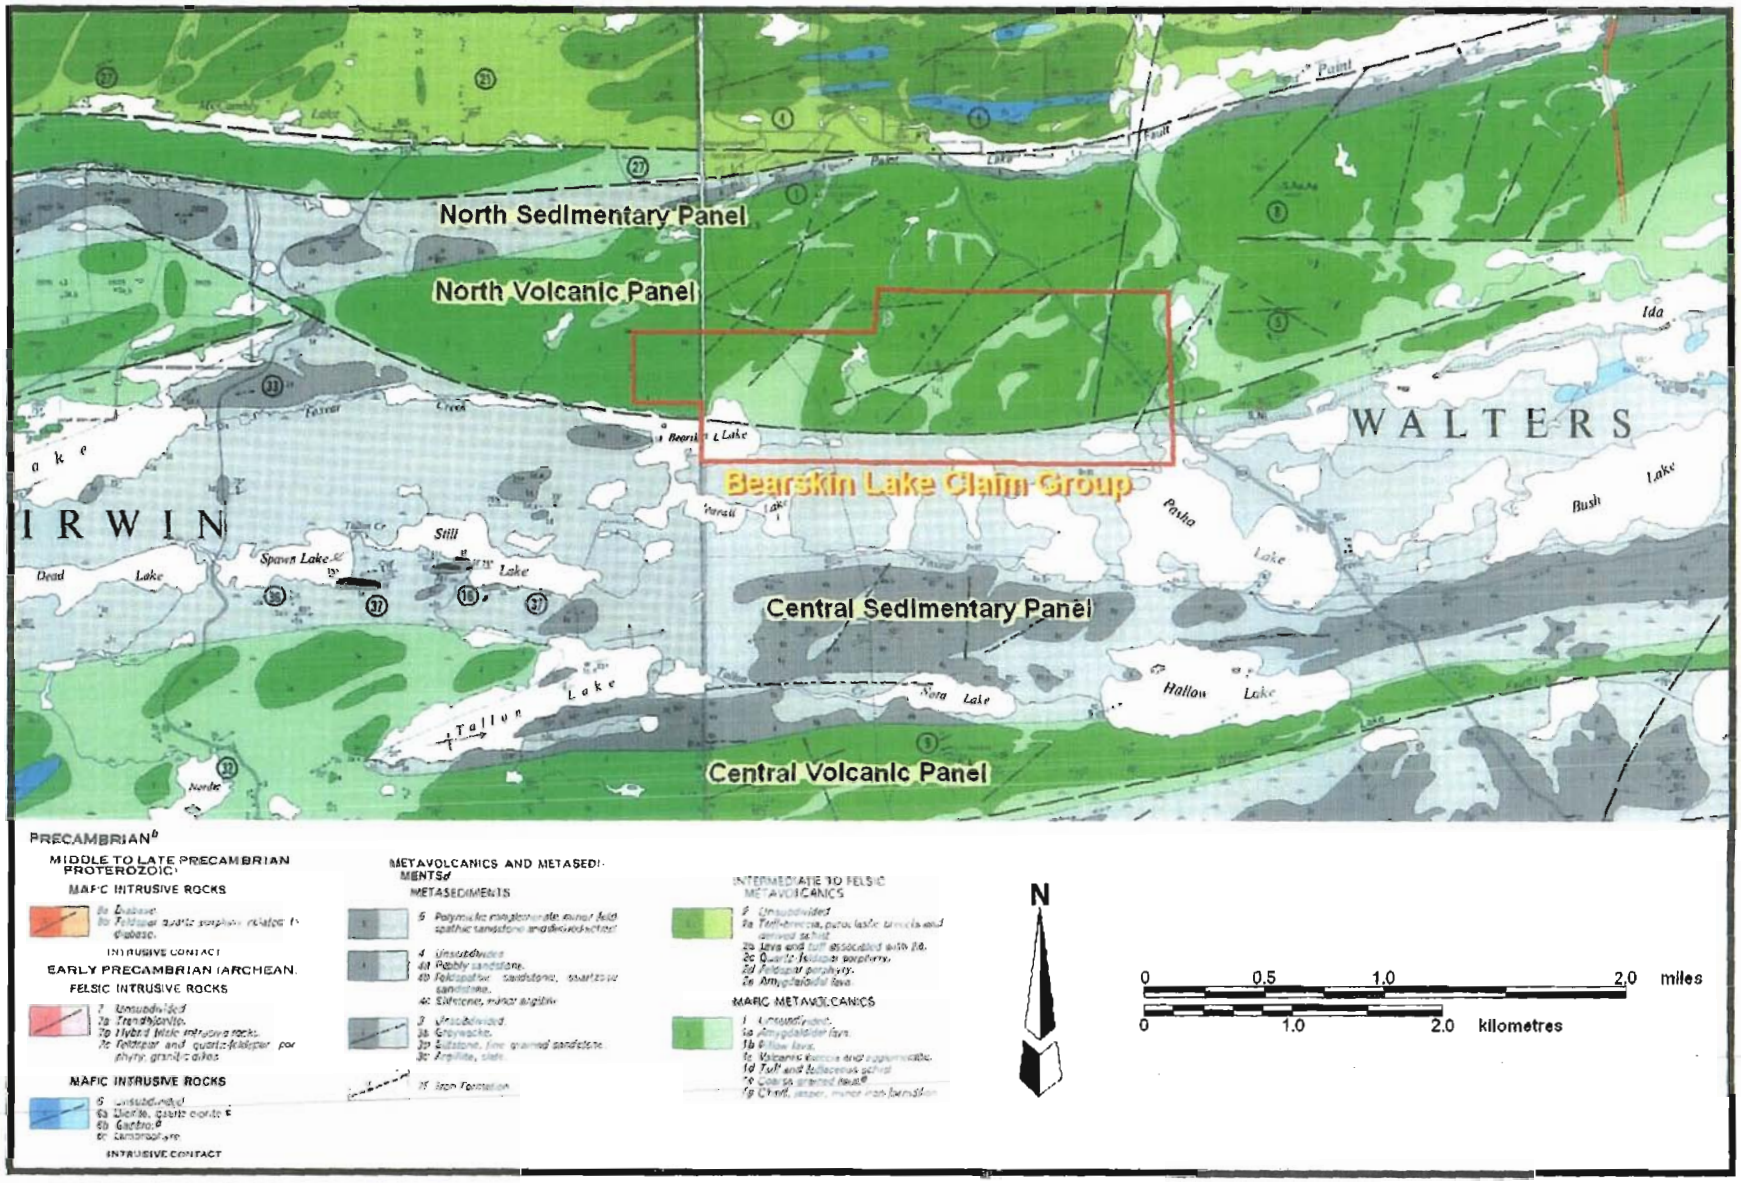

Figure 4: Geological setting of the Bearskin Lake claim group (modified after Mackasey (1975; 1976).

fault in the Oxaline Lake area suggests the fault is may be associated with the D_2 compressional event. D_3, the final event, was regional transpression resulting in a steeply dipping, penetrative regional cleavage. Since all beds were near vertical by the beginning of this event, there was no associated regional folding.

LOCAL GEOLOGY

The Bearskin Lake claim group is situated on the contact between the north volcanic and central sedimentary panels as described by Lafrance et al (2004). Within the property the contact between the two panels is defined by a shear zone known as the Bearskin Lake Fault, (Pasha Lake Fault?). This zone is up to 60 metres wide, is generally situated within the mafic volcanic panel and is characterized by the development of chlorite-sericite schist. Bowdidge (2000) suggested that the airborne magnetic survey indicates the Pasha Lake fault may be an extension of the Brookbank Fault and that movement along the fault could be right lateral displacement for up to 4 kilometres.

The mapping by Wade et al (1987a and 1987b) showed the west portion of the current claim group is underlain by predominantly fine grained massive mafic volcanics with occasional pillowed and amygdaloidal flows. Units cut by occasional fine grained, magnetite-bearing dykes flanked by mafic, fine grained feldspar porphyry, and occasional quartz diorite to gabbro intrusives and late-stage, north trending diabase dykes.

In the south are metasedimentary units consisting of predominantly polymict conglomerate and lesser sandstone. Exposure of these sediments is essentially non-existent due to the thickness of the till cover.

East west trending white quartz veins with patchy sulphide mineralization (pyrite, chalcopyrite, galena) are not uncommon and are found throughout the claim group. Widths of the veins are 0.75 to 1 metre but can be up to 1.5 metres.

Foliation was 070-100° with a steep north dip.

Metamorphism in the area has attained biotite grade of the greenschist facies.

2008 PROSPECTING PROGRAM

From 10 June to 04 October 2008, the Bearskin Lake claim group was systematically prospected by a number of Kodiak Exploration field crews. In total, 45 man-days were spent exploring the property. This work generated 117 samples for Au and the suite of elements indicated in Appendix "C". All observed quartz veins, as well as mineralized mafic volcanic horizons were sampled. Existing trenches found on the property were also sampled.

The prospecting traverses were generally run in a north-south direction across the local strike. These traverses covered the entire claim group from boundary to boundary. Daily GPS plots of these traverses along with the sample locations are presented in Appendix "B" along with the sample descriptions. A 1:5000 scale map showing all sample sites is in the rear pocket.

RESULTS AND DISCUSSION

The prospecting and sampling of the Bearskin Lake claim group identified or confirmed one strong gold showing in the northeast portion of claim 1217196, and three weak gold showings in the northeast portion of the claim group. Additionally, a number of samples throughout the property returned enhanced copper values (>0.1% Cu).

The gold showing on claim 1217196 returned gold values from 1 to 34 gpt. The gold is hosted in an east trending quartz vein with a dip at 55°N. The quartz is hosted by a local chlorite-sericite schist and pyritized mafic volcanics. Accessory minerals in decreasing order of abundance include pyrite (10+%), arsenopyrite and galena. There appears to be no major structural feature associated with this showing.

The three weak (0.1 to 0.2 gpt.) gold occurrences are situated in the northeast corner of claim 1204962, the centre of claim 1204966 and the east central part of claim 1204960. The latter occurrence is in a 1.5 metre wide, barren looking quartz vein striking east-west and dipping to the north. The first two occurrences are both within mafic volcanics containing disseminated pyrite (estimated 5%).

Copper values >0.1% Cu were not uncommon and are associated with either the chlorite-sericite schist of the Bearskin Lake Fault or in nearby mafic volcanics hosting disseminated sulphides. Some occurrences consist of quartz veins containing clots of massive sulphides. Chalcopyrite with or without galena is the common mineral, although malachite staining was noted on some of the quartz veins.

The analytical results and the analytical techniques employed are appended (Appendix "C") and a table of expenditures for the program is presented in Appendix "D".

CONCLUSIONS

There are indications of separate copper and gold mineralizing events. Although copper values were returned from the auriferous quartz veins, there appears to be a larger copper horizon within the pyrite-bearing mafic volcanics trending in an easterly direction across the central portion of the claim group. No significant gold values have yet been found in association with this horizon.

The strongest gold showings are hosted in quartz veins which display significant sulphide mineralization with pyrite being the most common. There is some copper mineralization associated with some of these veins.

The location of the strong gold occurrence in claim 1217196 suggests that it may be hosted by a local structural break which may inhibit the potential for the generation of the volume necessary for a commercial deposit.

RECOMMENDATIONS

The presence of separate gold and copper horizons warrants further investigation. A property wide cut and chained grid oriented north-south followed by detailed geologic and structural mapping

should better define these horizons and potentially identify future drill targets. If the cut grid from 1998 can be reoccupied, it would provide a link between past and future surveys.

With the shear hosted Brookbank deposit located approximately 7 kilometres to the west-northwest, work should focus more on the Bearskin Lake Fault, which may be a splay of the system hosting the Brookbank deposit. The presence of thicker till cover in the south portion of the property in the vicinity of this fault will require mechanical stripping of the shear zone followed by mapping and channel sampling. Mechanical till sampling or selective leach geochemistry should be investigated for exploring the areas of thick till cover.

The strong gold showing on claim 1217196 should undergo detailed structural mapping. The showing appears to be centred on local structural breaks. The extent of these breaks should be determined as should the potential of these breaks. Mechanical stripping followed by mapping and channel sampling is seen as the best way to determine the potential of this showing.

Further mechanical stripping, channel sampling and mapping should be carried out to better define the occurrences of copper in the mafic volcanics.

A proposed cost for the above recommended work is presented in Appendix "D".

REPORT **A08-4023**

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:
A representative 500 gram split is seived at 100 mesh (149 micron) with assays performed on the entire +100 mesh and 2 splits of the -100 mesh fraction. A final assay is calculated based on the weight of each fraction.
Values which exceed the upper limit should be assayed for accurate numbers.

REPORT **A08-6886**

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:
A representative 500 gram split is seived at 100 mesh (149 micron) with assays performed on the entire +100 mesh and 2 splits of the -100 mesh fraction. A final assay is calculated based on the weight of each fraction.
Values which exceed the upper limit should be assayed for accurate numbers.

ASSAY CERTIFICATES

The assay certificates were part of the original submission (Submission Number 2.39430).

ANALYTICAL METHODS

Sample Prep

Up to 5 kilograms of the sample is crushed with up to 75% passing 2 mm. A 250 gram split is pulverized (hardened steel) to 95% passing 105 micron.

Analyses

Code 1A3 - Au Fire Assay - Gravimetric Finish

A 1 assay ton (29.167 grams) sample is mixed with flux (borax, soda ash, silica) and litharge (PbO) with Ag added as a collector. The sample with the flux is then added to a crucible, placed in a 1050°C assay furnace and left for a predetermined time, to melt or "fuse" the contents of the crucible. The crucibles are then removed from the assay furnace and the molten slag (lighter material) is carefully poured from the crucible into a mould, leaving a lead button at the base of the mould. The lead button is then placed in a preheated cupel which absorbs the lead when heated to the melting point, leaving only a tiny metal bead of Ag (doré bead) which contains Au. Au is separated from the Ag in the doré bead by parting with nitric acid. The gold flake remaining is weighed gravimetrically on a microbalance.

(Hoffman,E.L. , Clark, J.R. and Yeager, J.R. 1998. Gold analysis - Fire Assaying and alternative methods. Exploration and Mining Geology, Volume 7, p.155-160.)

Element	Detection Limit	Upper Limit
Au	0.03	1,000

Code 1A3 (Fire Assay-Gravimetric) Detection Limits (g/tonne)

Code 1E3 – Aqua Regia - ICP-OES

0.5 g of sample is digested with aqua regia (0.5 ml H_2O, 0.6 ml concentrated HNO_3 and 1.8 ml concentrated HCl) for 2 hours at 95°C . Sample is cooled then diluted to 10 ml with deionized water and homogenized. The samples are then analyzed using either a Varian VISTA PRO, Varian 735-ES or Perkin Elmer OPTIMA 3000 Radial ICP for the 37 element suite. A matrix standard and blank are run every 13 samples.

A series of USGS-geochemical standards are used as controls. This digestion is near total for base metals however will only be partial for silicates and oxides.

The detection limits are tabulated below.
