1.0 EXECUTIVE SUMMARY

In April 2010, Queenston Mining Inc. ("QMI" or "the Company") acquired the Lebel Gold Property as a result of the amalgamation with Vault Minerals Inc. The Property hosts the former Bidgood #2 Mine that between the years 1934-1951 produced 165,000 oz. of gold at a recovered grade of 9.2 g/t Au. In addition, several other gold targets exist on the Property and, as such, are identified in this Report.

From May 2010 to December 31, 2011, QMI completed 209 drill holes having 42,909m of coring on the Property. The diamond drill programs were designed with the following anticipated results;

- to develop a near surface gold resource at the former Bidgood #2 / Moffat-Hall Mines, currently labeled the South and North Zones, targeting historic vein trends,
- to develop a near surface gold resource at the Boundary Zone,
- to follow-up explore for gold-copper mineralization within the KQS quartz-feldspar intrusive setting as discovered at Mud Lake and Bidgood #1 Mine vein trends,
- to follow-up on the possible 'Kirkland Main Break' trend at the north edge of Mud Lake.

As a result of the 2010-11 diamond drill initiatives along with historic drilling, on October 17, 2011 QMI announced a National Instrument 43-101 resource on the Bidgood and Boundary areas of the Lebel Gold Property, representing the first resource calculated since the closure of the Bidgood Mine in 1951. In addition and as a result of the 2010-11 drill programs, new gold-veins have been discovered within and to the south and north of the South and North Zones and beyond former mined veins. In regards to the North Zone, 2010-11 drilling has intersected multiple gold veins in preparation for future resource definition drilling.

The highlight of the Mud Lake drill program is provided by the ML11-13 gold intersection of 1.5 g/t over 15.5m that may represent the east projection of the 'Kirkland Main Break' in Lebel Township.

Further exploration recommendations are provided for proposed diamond drilling of the North and South Zones to further develop gold resources. Diamond drilling is also proposed for other Property targets.

2.0 INTRODUCTION

2.1 GLOSSARY AND ABBREVIATIONS

">", "<"	greater than, less than
"AAS"	Atomic Absorption Spectroscopy
"AA"	is an acronym for Atomic Absorption, a technique used to measure metal content subsequent to fire assay
"asl"	above sea level
"ASD"	Analytical Spectral Devices Inc. Fieldspec Pro
"Au"	gold
"C"	degrees Celsius
"cm"	centimetres
"E"	east
"el"	elevation level
"ft."	foot or feet
"g/t Au"	grams per tonne gold
"Goldaur"	Goldaur Resources Inc.
"Goldcorp"	Goldcorp Canada Ltd.
"ha"	Hectare
"KLEGP"	the Kirkland Lake East Gold Project
"KLGC"	the Kirkland Lake Gold Camp
"KLMB"	the Kirkland Lake Main Break
"km"	kilometre
"LLB"	Larder Lake Break
"LLDZ"	Larder Lake Deformation Zone
"m"	metre(s)
"M"	million(s)
"Ma"	millions of years
"mm"	millimetre(s)
"MNDM"	Ontario Ministry of North Development and Mines
"M&SR"	mineral and surface rights
"MR"	mineral rights only
"N"	north
"NE"	northeast
"NI"	National Instrument
"NTS"	National Topographic System
"NW"	northwest
"NSR"	an acronym for net smelter return, which means the amount actually paid to the mine or mill owner from the sale of ore, minerals and other materials or concentrates mined and removed from mineral properties, after deducting certain expenditures as defined in the underlying smelting agreements
"OGS"	Ontario Geological Survey
"oz/T"	troy ounces per short ton
"Placer"	Placer Dome (CLA) Ltd.
"Polymet"	Polymet Resources Inc., in Cobalt Ontario
"Property"	the Lebel Property
"ppb"	parts per billion
"ppm"	parts per million
"Queenston"	Queenston Mining Inc.
"S"	south
"SE"	southeast

“SW”	southwest
“Swastika Lab”	Swastika Laboratories Ltd., in Swastika, Ontario
“t”	tonnes (metric measurement)
“TN”	True North
“tpd”	tonnes per day
“UTM”	Universal Transverse Mercator
“Vault”	Vault Minerals Inc.
“W”	west

3.0 PROPERTY LOCATION, DESCRIPTION AND LAND TENURE

3.1 LEBEL PROPERTY LOCATION

The Property is located in the south central region of Lebel Township, District of Timiskaming, in the eastern part of Northern Ontario, Canada. The geographic centre of the Lebel Property is approximately 48° 09' 47" North Latitude and 79° 54' 49" West Longitude. King Kirkland is located at the western property limit and Kirkland Lake, a historical gold mining town with an approximate population of 10,000, is located approximately 6 km to the west. The Property is approximately 500 km north of Toronto, 200 km north-northeast of Sudbury and 120 km southeast of Timmins.

3.2 LEBEL LAND TENURE DESCRIPTION

The Lebel Property comprises of 31 patented claims with mining and/or surface rights, 3 licences of occupation mining rights only, 3 leases with mining and/or surface rights and 21 unpatented claims that together cover an area of approximately 1,198 ha. Queenston owns 100% interest in the Lebel Property and all the patented claims are in good standing in perpetuity subject to annual Ontario Provincial mining taxes and surface municipal property taxes. Most of the unpatented claims are in good standing until 2015. Queenston has sufficient banked assessment credits to maintain its unpatented mining claims in good standing for many years. The Ontario crown and private interests own the unpatented claims' surface rights. The boundaries of individual claims can be identified in the field by locating claim posts. The claim boundaries have not been surveyed.

There are no current title defects affecting any of the Lebel Property mineral claims. Some of the Lebel claims are subject to Net Smelter Return royalties ranging up to 2%.

The Lebel Property forms part of Queenston's Kirkland Lake East Gold Project or KLEGP and is contiguous with two other Queenston properties; the Pawnee property to the south-west and the Commodore/Morris Kirkland Newstrike Resources Ltd – Queenston joint venture property to the south east.

In March of 2010, Queenston announced an amalgamation of 2236019 Ontario Inc., a wholly owned subsidiary of Queenston, with Vault. The newly amalgamated company continued operating under the name Vault Minerals Inc. as a wholly-owned subsidiary of Queenston.

Figure 1. Regional Location Map

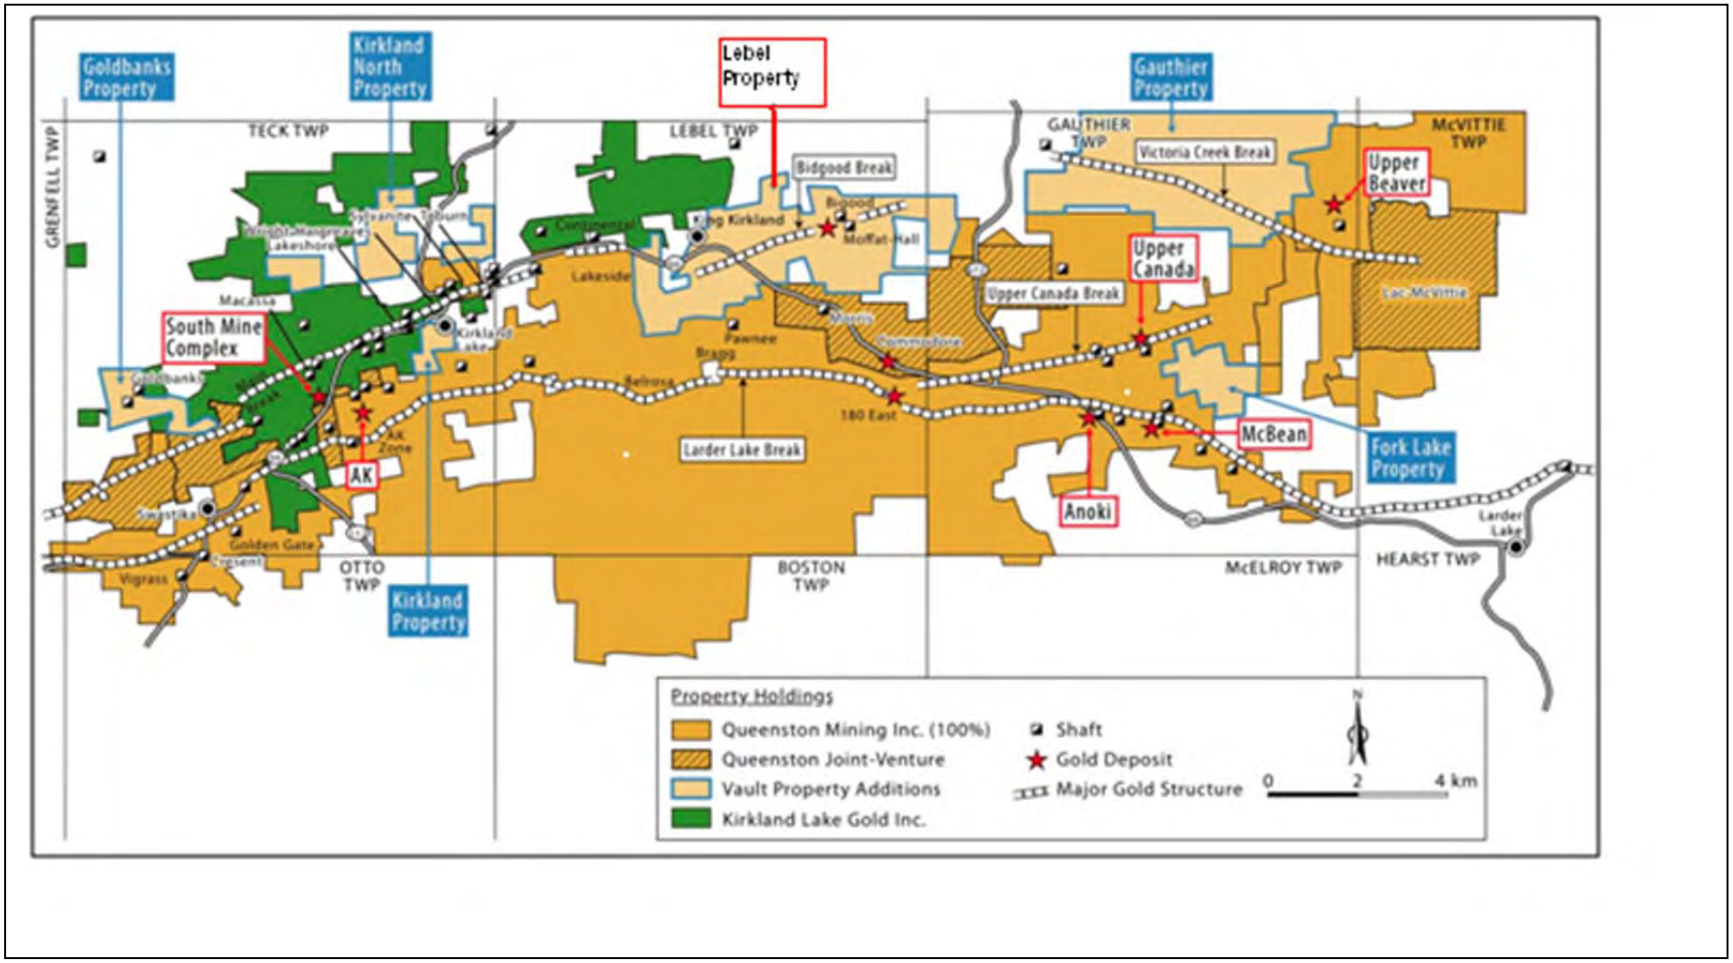

Figure 2. Regional Property Holdings Map

(Note: As of August 30, 2012, Queenston sold its 50% interest in the Teck Township Queenston-Kirkland Lake Gold Joint Venture claims to Kirkland Lake Gold Inc.)

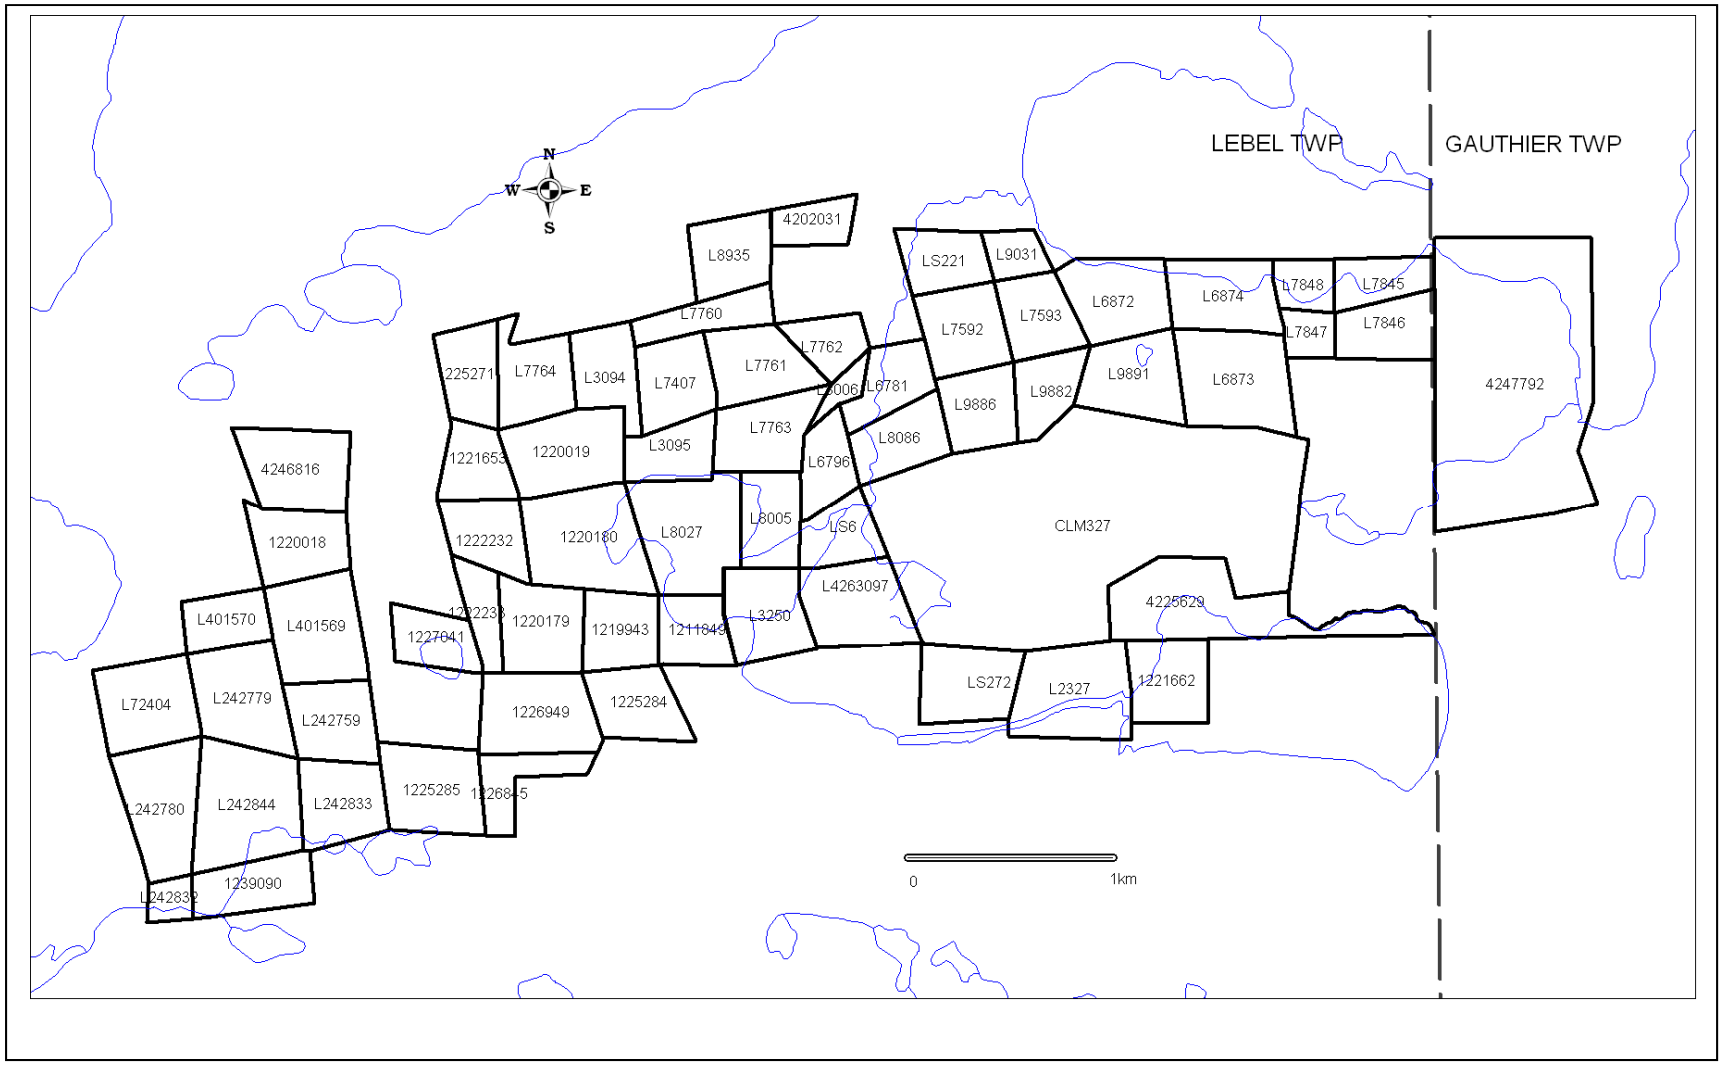

Figure 3. Property Claim Map

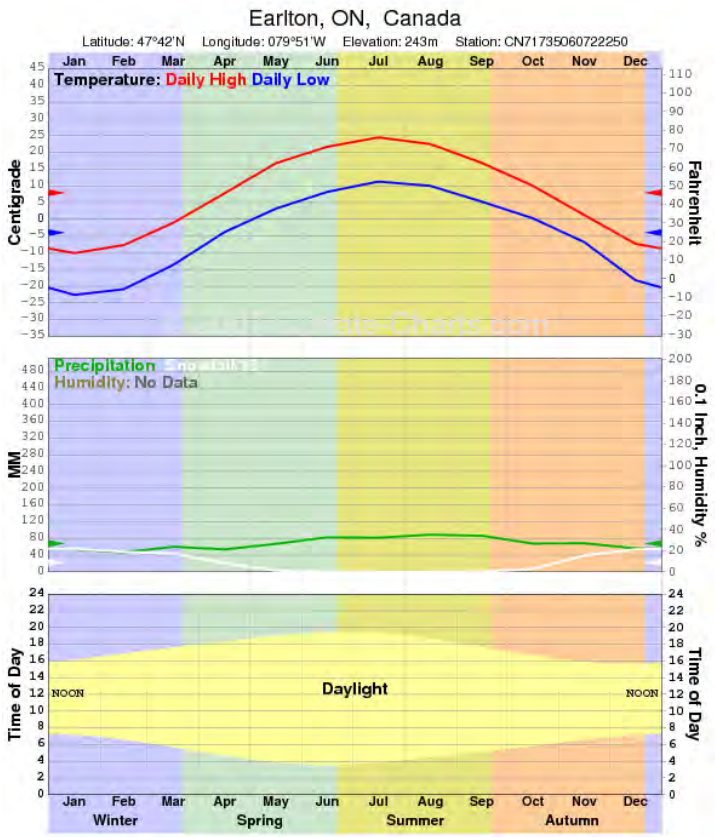
4.0 ACCESSIBILITY, CLIMATE, INFRASTRUCTURE AND TERRAIN

4.1 ACCESS



The property can be accessed travelling east from Kirkland Lake on paved Highway 66, which transects the property for approximately 2 km. Secondary and tertiary gravel roads, such as Bidgood, McTavish and Crystal Lake roads accessed from Highway 66 and historic trails, allow access to most locations on the property (see Figure 4.3). The historical road connecting Larder Lake to Kirkland Lake, known as the Larder Lake Road or Government Road, is now a mine-run trail crossing the property from the intersection point of the other roads due east. The property can be operated on a year-round basis.

4.2 CLIMATE

The climate in the region of the properties is that of a moderate northern temperate zone. Temperatures range from +30°C during the summer season and -40°C during the winter. Yearly precipitation averages are in the vicinity of 60 cm of rain and 250 cm of snow. The ground is generally snow covered from mid-November to mid-April.

The climate information presented in Figure 5.2 was taken from the weather station in Earlton, Ontario, located approximately 35 km south of the Lebel Property.

Climate trend data - Earlton, Ontario

(Source: www.climate-charts.com)

4.3 INFRASTRUCTURE

The Property is transected by Bidgood, McTavish and Crystal Lake roads which are, for the most part, maintained year-round and support vehicular travel. Other small trails can be traveled by ATV, snowmobiles or by foot. Telephone and high voltage power lines also transect the Property and nearby, the town of Kirkland Lake is also linked to the Ontario Power grid. An Ontario Northland Railway line also transects the south-western part of the Property and shipping facilities by rail are available at Kirkland Lake.

4.4 TERRAIN

Property elevation is generally 315m (McTavish Lake, south shoreline) to higher plateaus of 348m asl. Overburden cover is predominantly a veneer of glacial till typically ranging from 2 to 10 m thick with some areas of coarse grained, poorly sorted glaciolacustrine, organic swamp and the Bidgood mine tailings. The mine tailings range from 2 to 5m in depth. There is approximately 5 to 20% outcrop exposure on the Property.

5.0 HISTORY AND PREVIOUS EXPLORATION

5.1 EARLY REGIONAL HISTORY

The Kirkland Lake area has a long history of exploration and gold mining dating back to the turn of the 20th Century. Gold was first discovered in the region in 1906, specifically in the Swastika and Larder Lake areas. Production from the Gateford Mine and Swastika Mine began in 1910. Between 1910 and 2003, in excess of 40 million ounces of gold have been produced from 30 mines in the Kirkland Lake Mining District.

In 1911, W.H. Wright discovered gold near the northern end of Kirkland Lake. This led to other discoveries and culminated in the development of seven mines along the Kirkland Lake Main Break between 1912 and 1933; namely the Macassa, Kirkland Minerals, Teck-Hughes, Lakeshore, Wright-Hargreaves, Sylvanite and Toburn Mines.

5.2 PROPERTY HISTORY

The Lebel Gold Property represents of consolidation of eight mineral exploration properties that, until the late 1990's, were developed and explored by various companies and individuals. These properties include the Bidgood (including Bidgood #1 and #2 Mines), Moffat-Hall, Cambro (The Bouzan), Lebel Oro, King Kirkland, Kirkroyale (Kirk Conroyal), Lakeside Kirkland (Queen Lebel) and Gordon Lebel. In the late 1990's Goldaur Resources Inc. and later, Vault Minerals Inc. consolidated these individual properties into what is now known as the Lebel Gold Property. The Property consists of nine shafts, one past-producing mine (Bidgood #2), numerous surface showings and more importantly, a greater than 4 kilometer, linear, major structural system(s) that may be related to the Kirkland Lake Main Break.

A brief historical summary of these major sub-properties are provided.

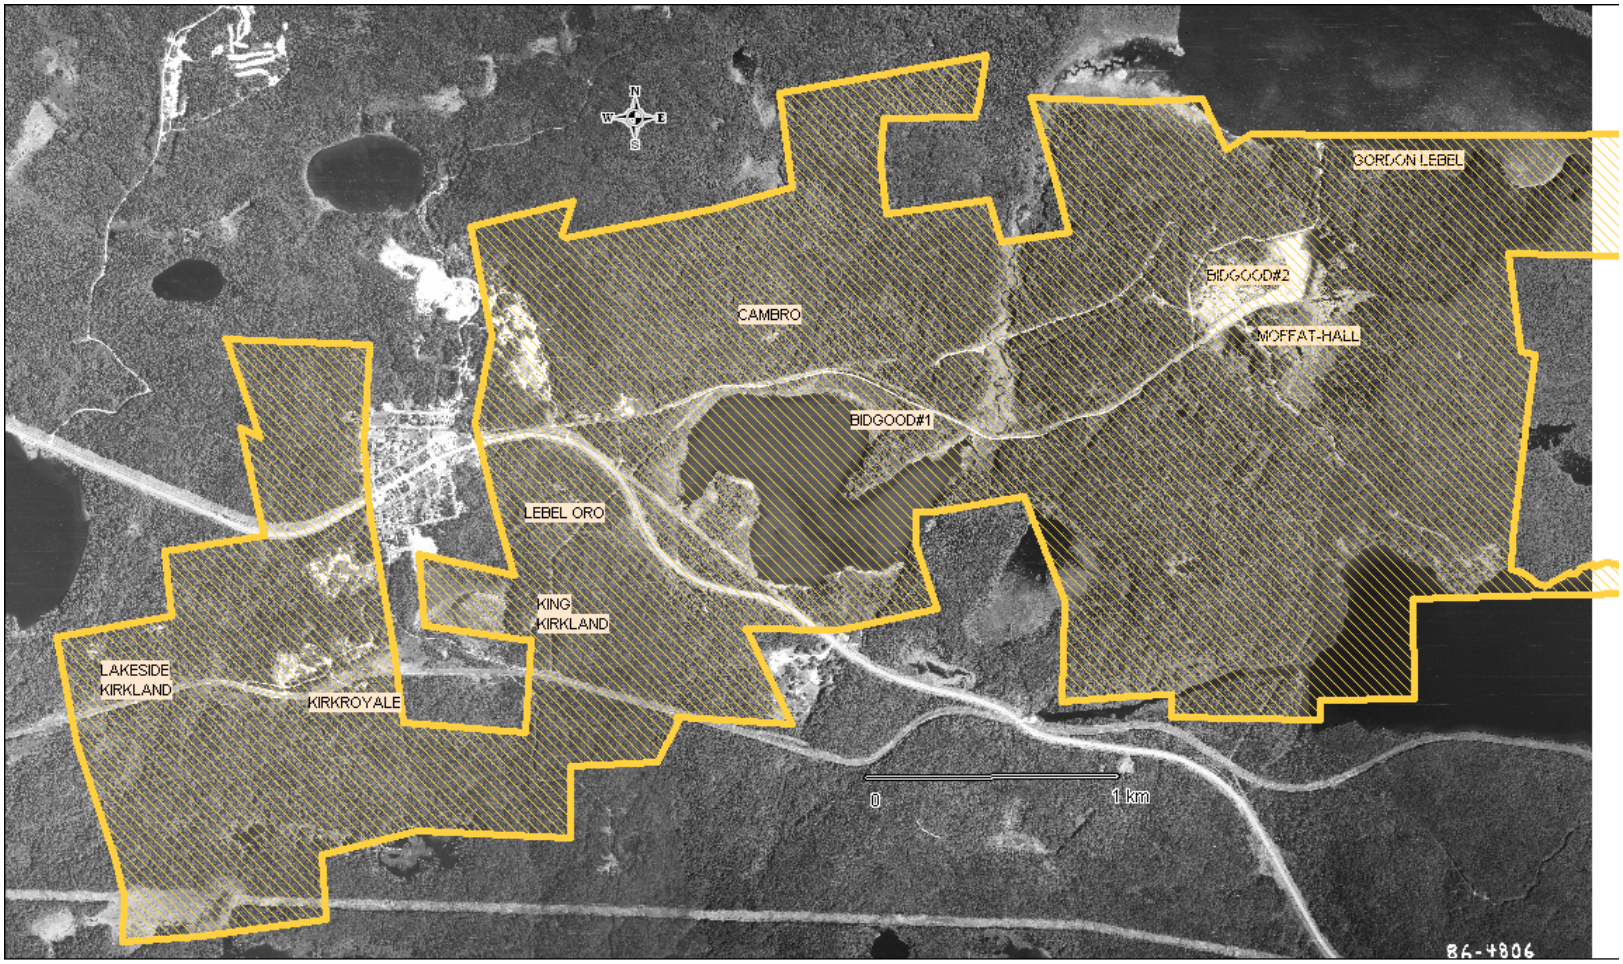


Figure 4. Lebel Sub-Properties

Bidgood #2 Mine

Development of the Bidgood #2 shaft commenced in 1928 following the discovery of free gold and telluride mineralization approximately 61 m west of the shaft. The shaft was developed to 150 m prior to suspending operations in 1931. Development and production operations resumed in 1933 with production coming from fourteen levels between 1934-49, and 1951 (Savage, 1964). A total of 16 levels were developed on 9 main vein sets to a depth of approximately 617 m, from the #2 shaft and from two winzes. A total of approximately 160,000 oz Au and 72,468 oz Ag were produced from 586,367 tons of ore at a recovered grade of 0.26 oz/t or 8.9 g/t Au (Parsons, 1980). Lytton Minerals optioned the property in 1987 and completed tailings sampling and 13 drill holes north and west of the shaft (Lytton Minerals, 1987). A letter recommending additional trenching in 1988 may have been part of this activity (Parsons, 1988). Vault completed an Induced Polarization survey over the property in 2004 that extended south over Moffat-Hall and southwest over Bidgood #1 mine (Walker, 2004).

Moffat-Hall Mine

The Moffat Hall property, current lease CLM327, was originally staked in 1917 and 1918. A 2-compartment shaft was developed to 167 m (550 ft.) in 1931-32. Approximately 853 m (2,800 ft.) of lateral workings were put in at the 150, 300, 425 and 550 foot levels. The mine closed in 1932. Between 1934 and -35, Bidgood Kirkland Gold Mines leased the Moffat-Hall and mined ore via a raise from Bidgood's 500 foot (152 m) level to Moffat Hall's 425 foot (129 m) level. Records show that 16,388 tons at a recovered grade of 0.29 oz/ton Au were extracted. Garfield "Red" Parsons, a key geologist who worked at the Bidgood mine, wrote a report on vein-ore control interpretation as well as mine lithology's and fault structures for both Bidgood and Moffat-Hall. This information is all that remains on record for the underground work. No underground drill hole information is available other than drill strings, underground level plan development and some colour geology available. The drill logs were apparently destroyed.

In 1954 Upper Canada Mines Limited completed trenching and drilled 12 holes on the Lebel Property. In 1967, Consolidated Virginia Mining Corporation carried out line cutting and re-sampled old trenches, followed by a 6 diamond drill hole program. The Moffat Hall property was staked by Mr. O'Connor in 1979 and optioned by the ENR Partnership which was absorbed by Silver Lake Resources Inc. Work done by Silver Lake included line cutting, magnetic, VLF-EM, IP surveys and diamond drilling of 43 holes near the Moffat Hall Mine, Blue Vein and Bidgood Break in 1981. In the late 1980's the property was explored by International Platinum. Later, Goldaur completed a trenching program and 9 diamond drill holes on a variety of targets.

Historical (non 43-101 compliant) high-grade drill intersections and surface channel samples (by Red Parsons) had returned: 124.8 g/t Au over 0.2 m, and 14.1 g/t Au over 1.0 m, while those representing open-pit potential include: 1.0 g/t Au over 36.5 m, 3.3 g/t Au over 10.2 m, and 1.4 g/t Au over 21.3 m.

Earlier drilling by Vault Minerals in 2003 returned 18.8 g/t Au over 0.93 m, 8.8 g/t Au over 1.15 m, and 30.6 g/t Au over 1.3 m, following up on a surface channel sample of 95.1 g/t Au over 2.7 m from the 85-1 (Blue Vein) Zone.

Bidgood #1 Mine

The Bidgood #1 mine was developed on the No. 9 vein, a quartz vein with variable disseminated pyrite, chalcopyrite, malachite, and telluride content. Several associated zones were delineated along a major feldspar porphyry and trachyte contact and grade was reported to be sporadic.

Bidgood Kirkland Gold Mines was incorporated in 1919 to develop the Bidgood #1 mine near Mud Lake and restructuring in 1923 resulted in property expansion and the development of the Bidgood #2 mine in 1928. Between 1919 and 1923, the Bidgood #1 shaft had been sunk to 180 m and 3 levels were opened up to test the No. 9 vein and the "blue vein" (Todd, 1928). The mine was dewatered in 1927 and exploration was carried out for 2 years. Operations were suspended in 1931 as resources apparently were transferred to the Bidgood #2 shaft.

King Kirkland Mine

King Kirkland Gold Mines was incorporated in 1920 following the discovery of a gold bearing vein by R. Montgomery in 1918 (Lovell, 1976). An inclined shaft was sunk on the No. 5 vein and a series of new veins were exposed on two levels from 1919 to 1921, primarily beneath King Lake. Tonopah Mining Company Limited completed additional drifting on the lower level in 1923. King Kirkland Gold Mines was reorganized into KirkKing Gold Mines Limited and the mine was dewatered, sampled and drilled in 1936.

Underground sampling of the 400 ft (122 m) level beneath King Lake delineated 1.0 g/t Au over 36.6 m and high grade zones were also delineated by drilling, including DD#5 from the 400 ft. level reported 10 g/t Au over 2.4 m (0.292 oz/ton Au over 8 feet, 4 feet true width) and DD #11, collared from the same location but with a 100 steeper dip intersected 10.3 g/t Au over 0.6 m (0.30 oz/ton over a core length of 2.0 ft), (Savage, 1964, ref. Craig, 1921 and Gillanders, 1937). Minor trenching and a single drill hole were completed in the 1970's with no reported results. In 1980 the Canadian Nickel Company Ltd. completed ground geophysics and two diamond drill holes near the King Kirkland prospect (Bennet, 1979).

A series of small programs were completed between 1982-94 by several junior companies and private entities. Surface geophysics, stripping, and two diamond drill holes extended the wide, low grade zone northeast of King Lake (K82-2 -1.2 g/t Au over 15.0 m) and higher grade mineralization defined in trenches at surface indicates the higher grade vein arrays may also extend along strike. A new showing, the Cliff Showing, was delineated to the east near the highway and several high grade values ranging up to 13.7 g/t Au over 0.91 m, (0.40 oz/t Au over 3.0 ft) were reported from surface sampling but two diamond drill holes failed to intersect mineralization at depth (Leahy, 1998).

Lebel-Oro Mine

The Lebel-Oro Mine consists of an inclined shaft sunk to 18 m in 1920 then deepened in 1923 to 61 m and opened up on two levels. The mine was dewatered in 1927 followed by 274 m of drifting and 137 m of crosscutting. Nipissing Mining Company optioned the property and completed 3 underground and 3 surface drill holes in 1928. Underground sampling obtained values ranging up to 50.7 g/t Au (1.48 oz/t Au) over 0.23 m (Lovell, 1976, ref. Todd, 1928). The shaft was dewatered a second time in 1936 and several underground and surface diamond drill holes were completed.

Geo-Technical Development completed surface mapping, geophysical surveys, and 8 diamond drill holes in 1948 (Leahy, 1998). New mineralization was intersected in the #3 hole 20.5 g/t Au over 0.43 m (0.60 oz/ton Au over 1.4 feet) and in the #4 hole 6 g/t Au over 0.39 m (0.18 oz/ton Au over 1.3 feet). Two additional sub-parallel zones were delineated immediately north of Lebel-Oro in 1984. A new vein located approximately 91 m (300 ft.) southwest of the Road Cut showing was trenched and sampled and values up to 30.6 g/t Au (0.90 oz/t Au) were reported from grab samples, (Parsons, 1984).

The Road Cut showing, a 20 m wide strongly altered, 050 azimuth trending deformation zone exposed on both sides of Highway 66, was sampled and drill tested. Outcrop and drill sampling failed to obtain high grade values of the road exposures. Sampling of highway fill float reported values ranging up to 10.3 g/t Au (0.30 oz/t Au) but was not sourced.

Kirk Royale Mine

The Kirk Royale shaft was sunk in 1924 and deepened the shaft to 140 m by a reorganized company in 1926. Additional work in 1928 included further deepening the workings via a winze to 340 m and development on two levels. Kirk Royale dewatered the mine in 1937 and completed additional sampling and diamond drilling. Additional drilling was completed in 1950 (1 ddh), and from 1959-63 by G. E. Harrison (10 ddh). T. Martin completed an additional 3 holes from 1971-72 (Lovell, 1976). No economic grades were reported from this activity.

The mine was dewatered, mapped and sampled by A.C.A. Howe International Limited in 1987 on behalf of Canadian Gold and Colray (Reukl, 1987). The work identified significant deformation and alteration along a major intrusive-volcanic contact with a minimum strike length of 76 m. Sampling obtained values ranging up to 5.47 g/t over 0.91m and larger lower grade zones ranging up to 1.83 g/t Au over 7.9 m.

Lakeside-Kirkland Mine

The Lakeside-Kirkland mine was originally developed by Queen Lebel Gold Mines Limited in 1921 that developed a 60 m shaft (No. 1 Shaft) on a quartz carbonate vein in claim L 2924. The Property was optioned to Anglo-Canadian Syndicate in 1923 and the shaft was deepened to 98 m, 180 m of development, and underground drilling.

In 1936 a second shaft was sunk west of the first and in 1938 it was deepened to 175 m and over 70 m of development was completed on two levels. Summary reports do not report grade

data, but indicate development of quartz-carbonate veins with disseminated molybdenite, pyrite, galena, sphalerite, and galena, which is typically associated with alkalic-type gold mineralization.

In 1941, the No. 1 shaft was dewatered, sampled, and drilled by Mining Research Corporation. At least 4 vein bearing zones were defined and underground drill values ranging up to 154.26 g/t Au (4.5 oz/t Au) over 1.5 m were reported (Mineral Research Corporation Limited, 1941). Single drill holes were completed in 1955 and 1962 by C. L. Bolland.

Cambro Shaft

Ontario Geological Survey map 53a (MacLean's) indicates the location of a shaft and a single drill hole extending south to the north shore of Mud Lake. This indicates that the development work was completed prior to his fieldwork in 1936. The shaft is located in a group of claims referred to by Lovell (1976) that originally were owned by Cambro Kirkland Mines Limited and that were sold to Bidgood Kirkland Mines Limited in 1929. Presumably the shaft work was completed prior to that date as there is no record in the Bidgood Mines data of any work on it. Goldaur completed surface sampling of the waste rock pile in 2000 but did not obtain any significant results (Leahy, 2000).

Gordon Lebel

Only two previous exploration programs were located in government assessment files. Gordon-Lebel Mines Ltd. completed 23 drill holes on the property from 1936-37. The results from the surface drilling that included holes ranging in depth from 201 to 1462 ft were not encouraging. The conclusions suggest there is potential at depth and that mineralization within the Bidgood #2 Mine may extend into the Gordon-Lebel property.

An undated report by Savage indicates two drifts on the 2025 ft level (617 m) of the Bidgood #2 mine were extended into the property and "…a small stope was mined out on the Gordon-Lebel property before Bidgood Kirkland Gold Mines closed down in 1949." A second Ontario Department of Mines report by Savage (Savage, 1964i) indicated "The stope was abandoned when the grade became too low."

Pamorex Minerals Inc. performed surface magnetometer and HLEM surveys followed by limited trenching and one diamond drill hole in 1990-91. The work was completed on CTL West target within in a large land package that extended north and east of the Bidgood #2 Mine property across McTavish Lake. A single trench and drill hole were completed on claim # L-6874. No significant values were obtained and no additional work was completed.

Lebel Gold Property – Consolidated Land Package 1997 to 2009

1997-2000:
Goldaur Resources Inc., a private company incorporated in 1997 began to acquire and consolidate property between 1998 to 2000 that would eventually become the Lebel Gold Property.

In 2000, five surface trenches were excavated on the 85-1 and Blue Vein Zones on the Moffat-Hall claim and returned gold values up to 95 g/t Au over 2.7m.

2003-2004:
In 2003, Goldaur merges with Vault Minerals Inc., a publicly listed company.
From November 2003 to January 2004, Vault completes nine NQ drill holes totaling 640 m designed to test the Moffat-Hall 85-1 Zone where 95 g/t Au over 2.7m was returned from surface sampling. All nine drill holes returned anomalous gold mineralization, >1g/t Au. A ground IP survey was completed at Bidgood #2 and at Moffat-Hall in 2004 and interpretation was provided.

2005:
On May 11, 2005 Vault Minerals Inc. enters into an Option Agreement with Placer Dome (CLA) Ltd. and later Goldcorp Canada Ltd. to explore certain claims on the Lebel Gold Property to earn an interest.

In 2005, Placer initiated the first surface exploration program on the consolidated Lebel Gold Property, without the Gordon Lebel, Simpson and some peripheral staked claims. Property scale surface mapping (including detailed structural interpretation), combined whole rock, petrography, ASD analysis, MMI soil and lake sediment sampling programs, as well as preliminary Bidgood Mine zone modeling was undertaken and recommendations for further work provided.

2006:
In the fall of 2006, a property scale drilling program was designed for the Lebel Gold Property consisting of 18 NQ size diamond drill holes (06-LB-001 to -018) totaling 2,786 metres with 1,631 drill core samples taken for Au and multi element ICP analysis. Drilling was completed in the following target areas:

Bidgood #2 Mine, Pipeline North, 85-1 Zone, Porphyry North, Bidgood #1 Mine, King Kirkland Mine

Highlights included 6.9 g/t Au over 1.0 m, 4.4 g/t Au over 2.8 m, 5.2 g/t Au over 1.0 m, and 16.3 g/t Au over 0.5 m.

The program was financed by Goldcorp as part of their earn-in considerations in regards to the Vault – Goldcorp Option Agreement. Analytical, descriptive, and modeling results were

reviewed, plotted in a variety of formats, and interpreted with conclusions and recommendations offered.

Outside of the Goldcorp-Vault Option Agreement, in the summer of 2006 Vault completed a surface mapping, surface line cutting, MMI soil sampling and two trenches on the Gordon Lebel Property. Observations, conclusions and recommendations were provided.

2007:
From May 30 to July 11, 2007 a 2,086 metre diamond drill program was completed from four drill holes LB07-19 to -22. The program was financed by Goldcorp and administered by Vault.

The drill program was designed to test for gold mineralization in epithermal splay & step-over veins spatially related to known shear-fault structures, namely the 85-1, Moffat-Hall, Main Bidgood and North Bidgood. Highlights included intersections of 14.1 g/t Au over 1.0 m, 8.3 g/t Au over 2.6 m, and 11.2 g/t Au over 1.0 m from the immediate mine area.

Recommendations for future exploratory work were provided.

2008:

Between January 19 to May 7, a twenty-drill hole program was completed with 5,236 m cored. Drilling was designed to test the Boundary, Discovery, Bidgood West Fault Array, Mud Lake and King Kirkland Zones. Goldcorp financed 3,859 metres of coring and Vault drilled the remainder on its 100% owned Gordon Lebel property situated along the north-eastern strike extent of several gold-bearing structures, including projected structures from the former producing Bidgood #2 gold mine. Vault's program tested the Boundary Zone, where prospecting identified several strongly-altered, mineralized shear zones, with grades up to 27.9 g/t Au over 0.3 m.

In 2008, drill hole LB08-35 intercepted two broad zones of up to 80% quartz flooding in a porphyry host and that returned 0.52 g/t Au over 17.8 m (456.2 to 474 m) and 0.83 g/t Au over 11.5 m (530 to 541.5 m). Drill hole LB08-36, located 100 m to the northeast of LB08-35, intercepted a shear zone returning 1.47 g/t Au over 3.0 m and may represent a related structural horizon. This shear zone, located under Mud Lake, was targeted due to anomalies delineated by 2005 lake bottom sediment sampling (Placer Dome). It became known as the KQS (Kirkland Quartz Stockwork) Zone. Drill hole LB08-40, located 700 m to the southwest of LB08-35, intersected an 8.7 m breccia zone from 154.5 to 163.2 m having up to 25% pyrite mineralization and returning 0.48 g/t Au over 4.5 m. 2008 drilling also intersected 10.2 grams of gold per tonne (g/t Au) over 1.1 m, 6.7 g/t Au over 1.4 m (within a zone grading 2.0 g/t Au over 13.7 m), and 7.3 g/t Au over 2.1 m (including 18.5 g/t Au over 0.6 m) at the Boundary Zone.

From September 8 to December 31, a diamond drill program was completed consisting of eight diamond drill holes (LB08-43 to -48 and extensions of 06-LB-016 and LB08-36) totaling 2,424 metres. The program was designed to test the KQS Zone at Mud Lake as intersected by drill hole LB08-35. -36 during the previous 2008 spring-summer drill campaign. Drill hole LB08-35 intercepted two broad zones with greater than 80% quartz flooding in a porphyry intrusive that returned 0.52 gAu/t over 17.8 m core length (456.2 to 474 m) and 0.83 gAu/t over 11.5 m core

length (530 to 541.5 m) with sections of fracture controlled pyrite, malachite and chalcopyrite. The hydrothermal system is analogous to quartz veining as intercepted in drill hole LB07-22 from 358.1 to 397.2m located immediately east of the past-producing Bidgood #2 Mine.

An overburden stripping program consisted of three trenches located west of the Bidgood #2 Mine having an aggregate surface cover removal of approximately 2,000 m3. The program was designed to expose the up-dip extension the quartz stockwork section as intersected in LB07-22.

Significant results of the trenching & drill programs are as follows;

At Mud Lake, drill holes LB08-35, 36 and 43 have identified a strong silica core (>80% quartz) within the larger QSZ with the following dimensions & grade:

strike: 510 m
depth: 350 m
width: 17 m (true widths not determined)
gAu/t: 0.46
gAg/t: 2.2
%Cu: 0.10

Surface trench TR08-11 uncovered a narrow fault trending 045 to 052 azimuth with eight grab samples returning an average of 37.9 gAu/t.

July to September 2009:

Between July and September, a four-hole drill program was completed through LB09-49 to -52 totaling 1,767 metres. The drill holes were designed to test the area between the King Kirkland Mine and KQS Zone.

Highlights from the program include drill hole LB09-49 returning up to 2.19 g/t Au over 5.15 m within a wider interval of 9.4 m grading 1.40 g/t Au, drill hole LB09-50 returning 1.12 g/t Au over 5.1 m and 1.91g/t Au over 2.05 m. Drill hole LB09-51 returned 0.92 g/t Au over 8.6 m on a porphyry-basic syenite contact, 300 m from the nearest drill hole, that intersected 11.2 g/t Au over 0.5 m and 5.3 g/t Au over 0.65 m in the previous drill program. Drill hole LB09-52 returned multiple gold anomalous zones, including 0.29 g/t Au over 49.05 m.

On November 17, 2009 Goldcorp allowed to lapse it's option agreement to acquire an interest in Vault's Lebel Gold Property with Vault retaining 100% title, right and interest to the Property. In November, Vault conducted surface stripping, mapping and sampling at 85-1, Blue Vein and Boundary Zones.

December 2009 to April 2010:

A diamond drill program, undertaken and financed by Vault, was designed to test the Boundary, Contact, Blue Vein and Bidgood Zones. A total of 67 drill holes were completed for a total of 5,584 m.

The Blue Vein and Boundary Vein were tested by drilling programs, with most drill holes designed for approximately 8 to 15 m centres, to assist in defining resources. Earlier trench channel samples returned up to 95.1 g/t Au over 2.7 m from the Blue Vein. The Blue Vein zone located 700 m south of the Bidgood Mine consists of at least 3 sub-parallel vein systems that are fault controlled. The BV1 occurs along a syenite-porphyry-wacke contact, while BV2 is completely contained within a porphyry body, at 420 metres west of BV1. Historic drilling (2003) includes intersections of 11.8 g/t Au over 2.8 m, 30.6 g/t Au over 1.3 m, 12.3 g/t Au over 1.1 m, and 18.8 g/t Au over 0.9 m to a depth of 100 m. The November 2009 Blue Vein trench channel samples returned 15.6 g/t Au over 1.8 m along 31 m from BV1 and 6.5 g/t Au over 3.1 m along 58 m on BV2, with sampling returned up to 73.0 g/t Au over 1.0 m. In early 2010, 23 shallow holes were drilled, totaling 1767 m, on BV1 and BV2. Hole BV10-23 on BV1 returned 7.7 g/t Au over 2.8 m (including 31.6 g/t Au over 0.6m), located 10 m west of previously reported hole BV09-04 that intersected 27.8 g/t Au over 1.4 m. On the BV2 area, hole BV10-18 returned 1.0 g/t Au over 32.8 m (including 9.6 g/t Au over 0.95 m) approximately 21 m to 45 m below surface. This intersection is located 90 m from historic (1989) intersection of 12.3 g/t Au over 1.1 m that formed part of a wide anomalous zone where sampling was incomplete. Other Blue vein drilling results include 14.3 g/t Au over 0.5 m (hole BV10-13) and 8.4 g/t Au over 0.85 m (hole BV10-8).

In 2009, surface trenching and chip sampling was undertaken on the Boundary Zone. It returned an average of 5.1 gAu/t across 3.0 m along an 18 m strike length with individual higher grade assays including 42.5 gAu/t over 0.4 m, 41.2 gAu/t over 0.5 m and 16.9 gAu/t over 0.6 m. A total of 32 shallow diamond drill holes (2979 m) targeted the Boundary Zone in late 2009, and into early 2010. The drill program reported 5.3 g/t Au over 5.75 m (within 3.4 g/t Au over 11.35m-hole B09-04) and 15.9 g/t Au over 1.0 m (within 5.5 g/t Au over 3.5m and within 1.7 g/t Au over 14.5 m-hole B09-13B).

At the same time as the Blue vein and Boundary vein were drilled by Vault Minerals, 9 holes totaling 837 metres were also drilled on two other targets, the Contact Zone, located 100 metres south of the Bidgood Mine and the Bidgood West , located 400 metres west of the Bidgood Mine. Results include 13.5 g/t Au over 0.8 m in the West Zone (hole BW10-01), and 2.9 g/t Au over 3.55 m in the Contact Zone (hole BC10-3).

In the winter of 2010, Vault performed a deep IP program over Mud Lake to assist in identifying possible mineralized targets at depth on the KQS Zone.

In April 2010, Vault amalgamated with Queenston and a diamond drill program started shortly thereafter in May 2010. This report is a summary of that drilling, which predominantly focused on targets within the Bidgood #2 Mine footprint and Boundary Zone.

6.0 REGIONAL AND PROPERTY GEOLOGY, MINERALIZATION

6.1 REGIONAL GEOLOGY

The KLGC occurs in the south-western portion of the Abitibi greenstone belt of the Archean Superior Province of the Canadian Shield and the regional geological setting of the Kirkland Lake area is typical of many gold camps located within the Superior Province. The KLGC occurs on the southern limb of the regional Blake River synclinorium, the northern and southern limbs of which are truncated respectively by the Destor-Porcupine Fault ("DPF") and the Cadillac-Larder Lake Break ("LLB") with its associated deformation corridor (the LLDZ). The majority of the historical gold production in the Abitibi Greenstone Belt is spatially associated with these two major regional structures (Queenston, 2001 Annual Report).

In the Kirkland Lake area, the LLB is considered to be a major east-west trending thrust fault that developed along the contact zone between mafic and ultramafic rocks of the Larder Lake Group to the south and mafic volcanic rocks of the Kinojevis Group to the north. Through recent age dating and review by the Ontario Geological Survey, these rocks have recently reclassified as parts of Tisdale Group and the Blake River Group respectively.

Expansion along the LLB created a graben-like basin which was filled with calc-alkaline volcanic and clastic sedimentary rocks of the Timiskaming Group. Later compression of this region created parallel and splay faults in both the Timiskaming and Lower Tisdale Group (Larder Lake Group) rocks along which many of the gold deposits of the KLGC were formed.

Today the LLB represents an unconformity between the Lower Tisdale Group rocks to the south and a 0.6 km to 5 km thick section of Timiskaming Group sedimentary and volcanic rocks to the north. Both the major rock groups in the area have been intruded by gabbroic and mafic-felsic intrusions, the most prominent are the Lebel Stock, Otto Stock, Murdoch Creek Stock and the Round Lake Batholith (Queenston, 2008 Annual Information Report).

The Timmins-Kirkland Lake segment of the Abitibi Greenstone Belt has been divided into nine supracrustal assemblages, as described in Table 1. Assemblages are described in order of increasing age.

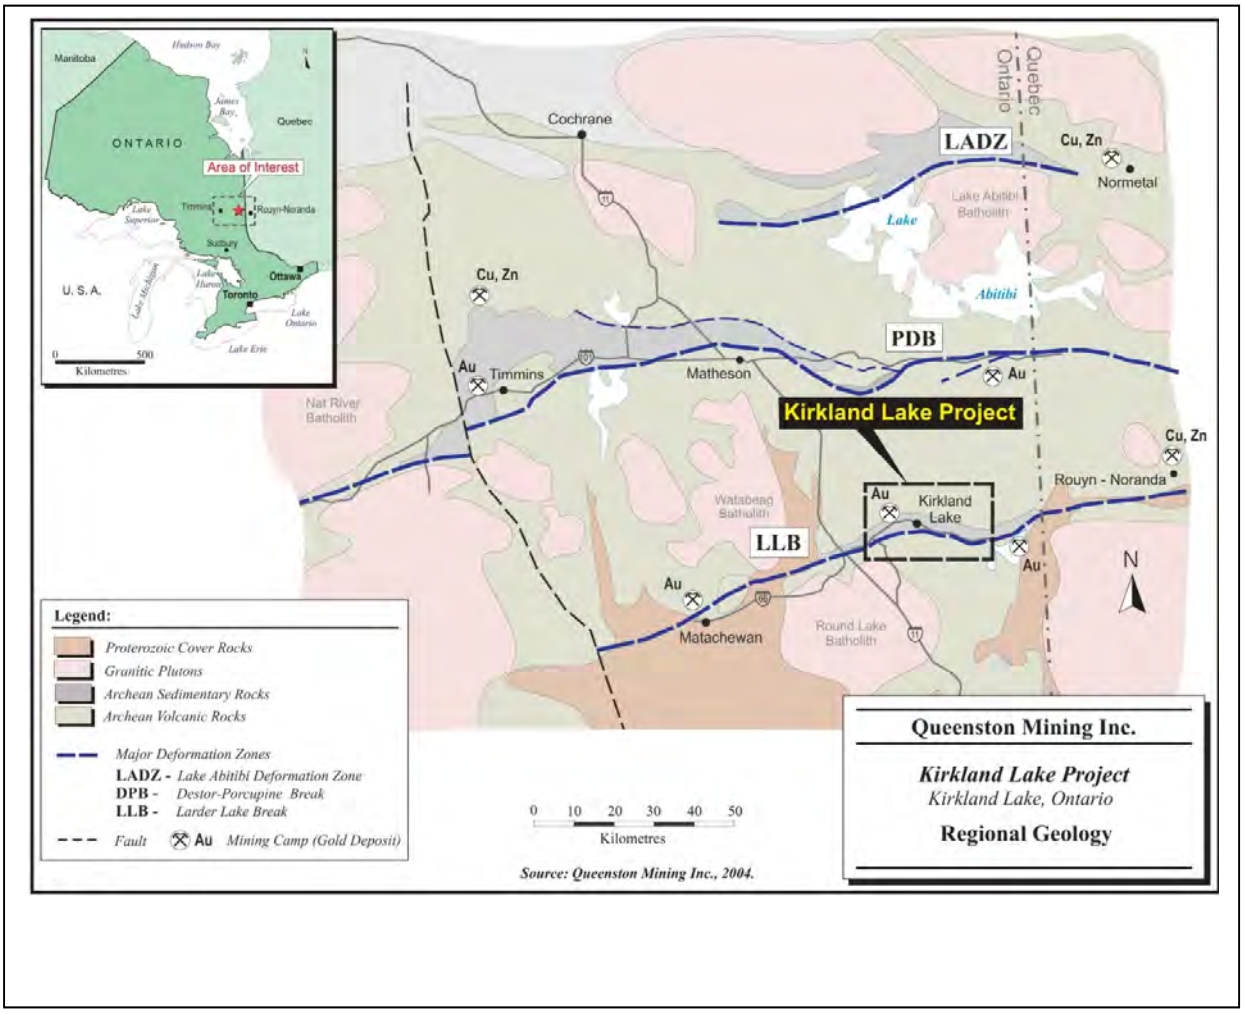

Table 1

SUPRACRUSTAL ASSEMBLAGES OF THE TIMMINS-KIRKLAND LAKE SEGMENT OF THE ABITIBI GREENSTONE BELT (SOURCE: RPA, 2004)

Assemblage	Description
Timiskaming	Contains sedimentary and alkali volcanic rocks including iron formation, such as Upper Canada and Macassa Mines.
Porcupine	Comprises sedimentary and calc-alkalic volcanic rocks including iron formation.
Upper Blake River	Comprised of mostly calc-alkalic volcanic rocks, such as at the Noranda Camp.
Lower Blake River (Kinojevis)	Comprised of mostly tholeiitic basalts, such as at the Holt McDermott Mine.

Upper Tisdale (Gauthier)	Comprised of calc-alkaline felsic to intermediate volcanics exhibiting flow and debris flow characteristics and associated volcaniclastics sediments.
Lower Tisdale (Larder Lake)	Comprised of mostly komatiitic, tholeiitic and calc-alkalic volcanic rocks and iron formation, such as at the Kerr Addison Mine, McBean Mine and Anoki deposits.
Kidd-Munro	Comprised of komatiitic, tholeiitic and calc-alkalic volcanic rocks.
Stoughton-Roquemaure	Comprised of komatiitic, tholeiitic and calc-alkalic volcanic rocks.
Deloro	Comprised of tholeiitic and calc-alkalic volcanic rocks and iron formation
Pacaud	Comprised of komatiitic, tholeiitic and calc-alkalic volcanic rocks.

Precious metal production in the Kirkland Lake Gold Camp has exceeded 40 million ounces (Risto et al, 2008) from 30 mines. Most of the gold production in the area has come from quartz veins associated with the Kirkland Lake Main Break ("KLMB"), which is interpreted to be a splay structure related to the LLB.

(Sourced from Agnerian, 2004)

Figure 5. Regional Geology

6.2 PROPERTY GEOLOGY

The Lebel property covers 7.7 km of the favourable Timiskaming Group of flows, tuffs and sediments with syntectonic dykes, sills and plugs of diorite, syenite and feldspar porphyry along strong structures that are splays off of the Larder Lake Break. The Main Break, the structure that hosts the seven big mines of Kirkland Lake, extends west of Teck township, where it is offset by the Murdock Creek fault. The offset portion is thought by Queenston geologists to extend through the Lebel property where it becomes the host structure for Bidgood ore. The Bidgood mine area hosts gold in dark grey quartz veins with associated molybdenum, massive pyrite veins (replacing magnetite), and locally chalcopyrite. There are at least 24 separate veins, all structurally controlled and all with haloes of further pyrite (+/- sericite, epidote, and leucoxene) that are also gold-bearing. These veins are splays off of two north-eastern trending structures known as the North Break, and the Main Break. The primary host rock is a diorite, and locally diorite breccias, with quartz-feldspar porphyry surrounding it and locally cutting through it as dykes. Basic syenite, and argillite are important hosts elsewhere on the property. The Cadillac-Larder Lake Break, which separates the Timiskaming and Tisdale assemblages in this area is located further south on the Pawnee and Commodore claims.

Lower Blake River (Kinojevis) Assemblage

Mafic Volcanic Flow

Mafic volcanic flows observed in the north end of the property are coarse grained and amphibolitic and may be coarse flows, mafic ash tuff, or amphibolitized flows. The rocks weather a medium grey-green and are medium to dark green on fresh surface.

Timiskaming Assemblage

Polymictic Conglomerate

The basal conglomerate is a polymictic conglomerate that according to MacLean (1956) contains jasper clasts and represents weathering of exposed basement at the onset of deposition of the Timiskaming assemblage. Jasper clasts were found in most of the conglomerate units during the 2005 mapping program.

Polymictic conglomerate varies from clast to matrix supported, and contains up to 50% subangular to subrounded clasts that range in diameter up to 15 cm but typically average about 4 cm. Clast composition is extremely variable but typically includes syenitic intrusion variants, basement lithologies such as mafic volcanic flows, magnetite iron formation, jasper, with reworked tuffaceous material typically as matrix. The rocks typically weather light to medium grey-green but can vary to dark brown due to carbonate alteration and are typically medium grey-green on fresh surfaces, varying with clast content. Primary bedding is readily observable throughout the property and includes graded bedding, coarse to fine conglomerate bedding and conglomerate-wacke bedding. Many conglomerates have a weakly magnetic matrix.

Wacke

Wackes are typically fine grained versions of the polymictic conglomerate and range from coarse, pebbly wacke to fine grained silty wacke. The units weather medium grey-green to grey and are medium grey to grey-green on fresh surfaces. Thin (2-10 mm) laminae are common and graded bedding was observed locally. Most of the wacke units mapped are located along the southwest corner of the property within the LLDZ deformation zone and are typically well altered.

Argillite

One argillite unit is found in the immediate vicinity of the Boundary Zone. It is an aphanitic olive green mudstone with bedding, and commonly with rip-up angular clasts.

Trachyte - massive, porphyritic, amygdaloidal

Trachyte flows are extremely variable due to primary composition that varies from mafic to felsic, and due to superimposed alteration. Trachyte flows weather medium grey and are dark to light grey, green, pink, dark purple and brown on fresh surfaces. Massive flows occasionally contain 2-10 mm bands assumed to be flow banding or flow related textures.

Porphyritic flows can contain up to 60% phenocrysts. Mafic porphyritic flows typically contain up to 25%, 2-5 mm augite, but can also contain up to 15% aegerine or pigeonite that weather recessively. Intermediate to felsic porphyritic flows are mineralogically diverse and contain variable amounts of pseudoleucite (up to 60%), plagioclase (up to 30%), K-feldspar (up to 30%), leucite (up to 7%), and nepheline (up to 7%). Amygaloidal varieties occur locally and contain up to 10%, <10 mm carbonate amygdules. Epidotization, hematization, carbonatization and chloritization of trachyte flows is common. Magnetic varieties are common, but magnetism does not appear to be related to hydrothermal alteration as relatively pristine units as well as altered units are magnetic.

Tuff – ash, crystal

Lapilli to ash tuff units are extremely variable in appearance ranging from grey to buff to purple-grey on weathered surfaces and medium green to grey to dark purple on fresh surfaces. Recessive weathering of the intragranular spaces is not uncommon. Individual beds can contain up to 20% crystals, which can include K-feldspar, plagioclase, and nepheline.

Tuff units typically have a granular texture but lack the micaceous and lithic content of wackes. Massive and bedded tuff varieties were observed with bedding typically ranging from 10-30 cm. Graded bedding was observed locally. Tuff units are variably magnetic.

Mafic Syenite (also basic syenite, lamprophyre)

Several mafic syenite units are indicated on Map 53a (MacLean) within the property. Several were sampled during the 2005 mapping program but only a few approach true mafic syenite by mineralogy or composition. The more mafic syenites typically contain up to 65% K-feldspar and up to 20% augite, weather medium to light grey, and are medium grey on fresh surfaces.

Variations include pink and green tinged varieties due to hematite and chlorite/epidote alteration, respectively. Several units of wide basic syenite have been discovered from drilling in the period 2008-2010; the 1944 government map does not show these units.

Syenite

Several intrusive rocks were mapped in the field as syenite. All weathered medium to light grey and were medium grey with <20% mafic minerals. Subsequent petrographic analysis indicates all are monzonite, comparable to the larger feldspar porphyry (Porphyrite) unit that extends through the south half of the property. Syenite units generally have a red brown to purple-red colour in core, are homogeneous, weakly to moderately magnetic locally, non carbonated and contain up to 5% black xenoliths.

Quartz Porphyry

There are several quartz porphyry intrusions adjacent to the gabbro intrusion at Bidgood #2

Mine, in the Boundary Zone area as well as a few immediately west of the property flanking mafic syenite intrusions that extend into the property. The quartz porphyry intrusions are similar to the feldspar porphyry intrusions elsewhere on the property, they weather light grey and are medium grey on fresh surface with colour variation due to alteration. Plagioclase is the dominant phenocryst, followed by amphibole and potassic feldspar. In core, they are always non magnetic, pale grey to white to light lime green in colour, competent, homogeneous, with 1-3% ubiquitous coarse disseminated pyrite, 1-5% chlorite fractures and consist of 30% anhedral 0.3 cm glassy-greenish quartz phenocrysts.

Bimodal Porphyries

The bimodal porphyries are relatively narrow, dyke-like units that are usually gold-barren, fresh, competent, homogeneous, brown-red to purple in colour, non-magnetic, non-carbonated, with 10% 0.6 cm euhedral feldspar phenocrsts and 30% feldspar 0.3 cm phenocrysts. Underground, lamprophye dykes are similar to the bimodal porphyries in that they are apparently late, having no gold content and having a “damming effect” on the gold-bearing fluids such that gold grades decrease away from them and the contacts are often mineralized.

Diorite

Several types of diorite are historically described on the property. The central stock is far more extensive than the 1944 government map indicates; recent drilling has uncovered its eastern extent at the Boundary Zone. It is the primary host of the Bidgood #2 and Moffat-Hall mines. The four sub-units described are diorite, ilmenitic diorite, epidote diorite, and diorite breccia. The diorite is a fine to medium grained unit that can occasionally grade into gabbroic textures. Feldspar groundmass holds 50% black mafics (chlorite after hornblende), often with alteration products of iron such as epidote, leucoxene, specularite, and on its southern contact, magnetite. It is usually highly magnetic. The ilmenitic and epidote diorites are also historical classifications, but they are intermixed with the other two units. There are variations in epidote content from rare to 3-5%, usually as clots and fracture-filling veins. The diorite breccia is found on the north

half of the stock (and locally on the west side) and consists of 10% -20% rounded breccia fragments up to 0.1 m with resorbed, rounded contacts. It is usually non-magnetic.

Feldspar Porphyry (Porphyrite)

The largest geological unit on the property is the feldspar porphyry, or Porphyrite of MacLean (1944). The rock weathers light grey and is typically medium to light grey on fresh surfaces and the weathering rinds often have an orange tinge due to weathered pyrite and/or ankerite.

The main intrusive body extends from the west end of the property where it is approximately 150 m wide, thickens east of King Kirkland in the Mud Lake area to approximately 1500 m and narrows further east to just under 1000 m at the eastern contact. The width of the main body narrows significantly where it intersects the Long Lake fault and it also has an apophysis that extends northwest along S2 folded stratigraphy. The unit has been grouped into a single, homogenous unit due to the mapping scale but detailed mapping around trenches by previous workers has shown the unit consists of multiple phases. Two separate varieties occur in the Bidgood #1 mine area, including a bimodal porphyry. More massive varieties, although still porphyritic, occur south in the King Kirkland and southwest of Moffat-Hall mine. Previous workers describe relict textures of conglomerate, trachyte, and sediments locally within the large unit, and conglomerate-like textures are present in 2005 Trench 4. However, these are considered roof-pendant type remnant features. Therefore, all occurrences were initially termed feldspar porphyry and subsequently modified by petrographic analysis.

QFP Feldspar Porphyry

The Quartz-Feldspar porphyry is a non-magnetic unit, often occurring as dykes, with 10%-30% anhedral 0.3 cm glassy-greenish quartz phenocrysts plus 10%-30% subhedral pinkish-white feldspar phenocrysts. Plagioclase is the dominant phenocryst. It sometimes contains rare dark grey xenoliths up to 0.6 cm. When altered, they are frequently sericitized.

6.3 MINERALIZATION CHARACTERISTICS

At Bidgood #2 Mine, gold and associated mineralization are found within veins numbered 1 to 21, and at Moffat-Hall are numbered 1 and 2. Subordinate splays are common and are often cited as carrying significantly higher grades. Mineralized veins commonly consist of massive coarse pyrite with local dark grey to dark blue quartz, typically combining for 1.3 cm to 0.3 m widths. Sometimes a calcite vein is intimately associated. Associate minerals but occurring to a lesser extent include silver, molybdenite, chalcopyrite, calaverite+altaite (tellurides), rare galena, tourmaline, and strontianite. For veins in the southern portion of the mine area, host diorite is highly magnetic, with frequent 0.3 cm magnetite veining, and 3-5% epidote. Within this southern area, the diorite is altered proximal to veining with;

- magnetite altering to coarse disseminated and vein pyrite (vein areas are generally non-magnetic, although locally magnetite is part of the mineralization);

- ilmenite altering to a light lavender and cream coloured leucoxene (localized to mineralized areas);
- epidote forming as spots, patches, streaks, stringers (both generally and with increasing percentage proximal to mineralized areas);
- saussuritization having weak to high bleaching plus silicification;
- weak hematization, and chlorite-silica veining forming and grading into the dark grey-blue quartz veins.

Free gold is present usually within the dark grey-blue quartz veins, rarely in pink-orange calcite veins, and also coating molybdenite slips/faults and coating massive pyrite veins. Gold is also found within inclusions in pyrite.

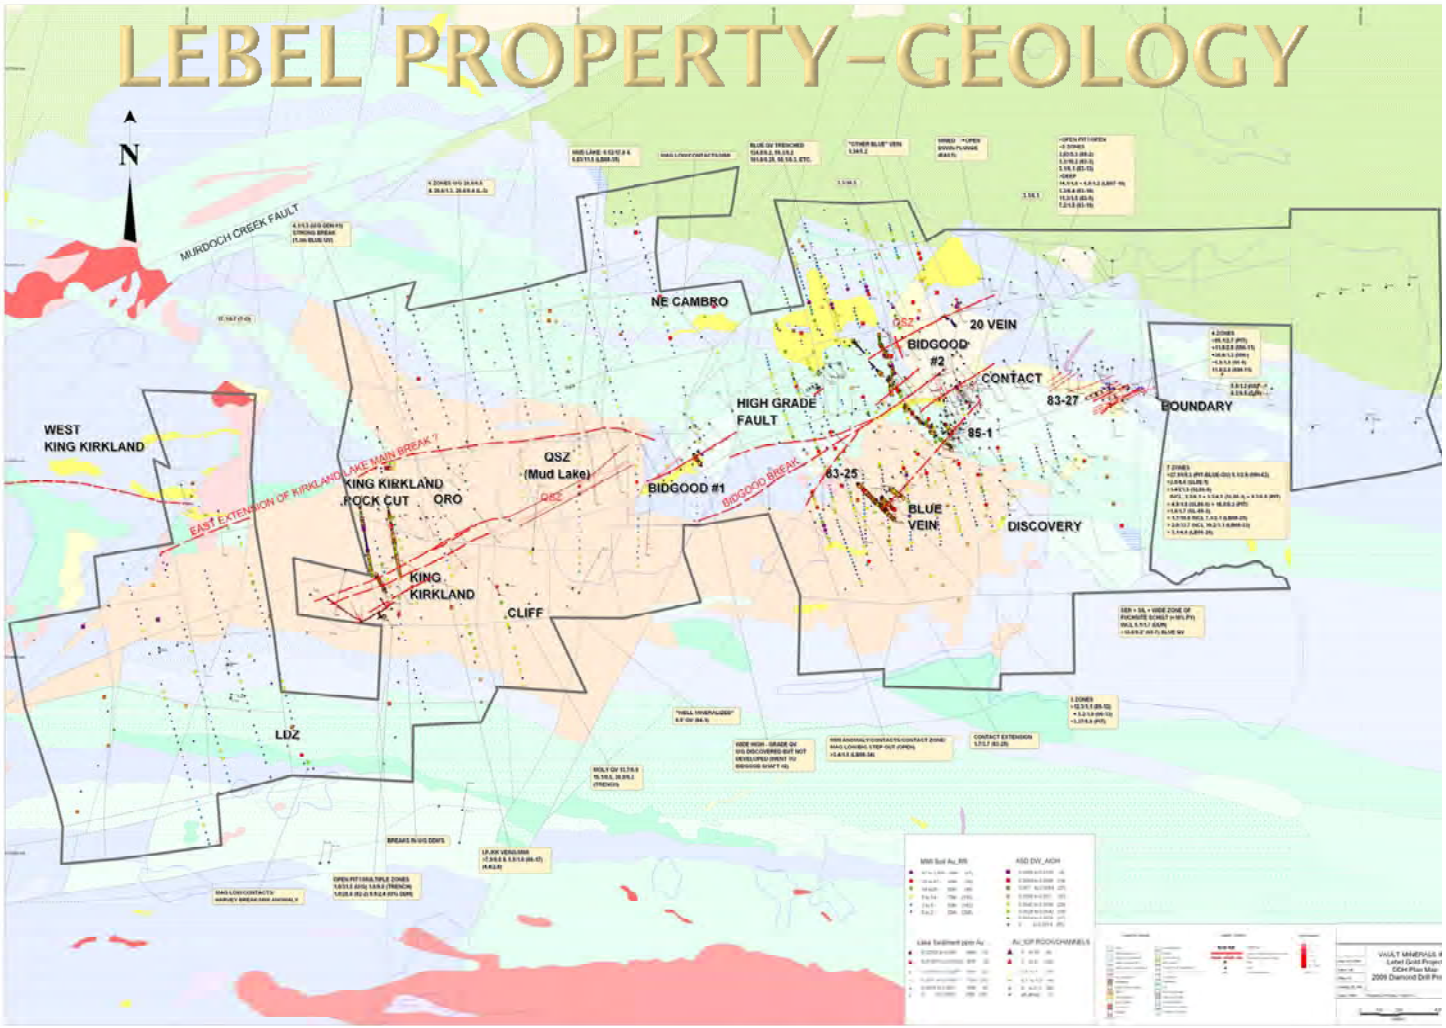

Figure 6. Property Geology

7.0 2010-2011 DIAMOND DRILL PROGRAM

7.1 2010 DIAMOND DRILL PROGRAM

From May to December 31, 2010, 95 drill holes were completed at the Bidgood #2-Moffat-Hall Mine complex for a total of 16,133.55 m. Coring came from drill holes BG10-01 to -33 (including BG10-18B, -18C), BG10-36 to -73, BG10-75 to -80, BG10-86, BG10-90 and BG10-92 to -105.

South Zone

Targets included multiple vein systems that were identified during the development of the production years and included the #1 and #2 Veins at Moffat-Hall and #15, #20, #6, #11 Veins at Bidgood #2 Mine. The target area is now identified as the "South Zone". Drill holes were designed, either collectively or singularly, to define near surface open-pit and deep higher grade potential of known vein trends.

North Zone

Approximately 225 m north of the South Zone and closer to the Bidgood #2 shaft, drill efforts focused on testing strike and plunge extensions of the #1, #2, #3, #12 and #14 Vein systems, now identified as the "North Zone".

Besides testing for known veins, the program also explored for new vein discoveries particularly immediately northwest of Bidgood #1, #2 and #3 Vein horizon.

Diamond Drill Company

In 2010, Cabo Drilling (Ontario) Corp.[1] performed all of the diamond drill activities at Bidgood.

7.2 2011 DIAMOND DRILL PROGRAM

South and North Zones

From March 10 to December 31, 2011, 91 drill holes were completed at the Bidgood #2-Moffat-Hall Mine complex for a total of 20,084.2 m. Coring came from drill holes BG11-34, -34A, 35, BG11-74, BG11-81 to -85, BG11-87 to -89, BG11-91, BG11-106 to -149 (including -112A, -113A, -114A), BG11-152 to -180 (including -153A) and BG11-182. Given that BG11-128 and BG11-139 have already been submitted for assessment work credits[2], only 18,806.2 m will be submitted for assessment work credits from this program.

2011 South Zone drilling was specifically planned to continue testing the Moffat-Hall #1 and #2 Veins and Bidgood #15, #20, #6 and #11 Veins with the intent of developing a near-surface 43-

[1] Cabo Drilling (Ontario) Corp. Box 998, 34 Duncan Avenue North, Kirkland Lake, ON P2N 3L3 Tel: (705) 567-9311

[2] Sutton, M. "Lebel Gold Project, Diamond Drill Report. BG11-128, BG11-139", March, 2012.

101 gold resource. On December 1, 2011 a NI43-101F1 Technical Report[3] for Bidgood South and Boundary Zones was signed and submitted and represented the first resource generated at Bidgood–Moffat-Hall since mine closure in 1951.

In regards to the North Zone, drilling followed up on zones discovered in 2010 mainly #12, #10, #14, #1, #2, and #3. Deep drilling was also initiated below the Bidgood's deepest level (2025 Level) to test the #21, #24 Veins as well as anomalous historical drill gold intercepts from that Level.

Boundary Zone

Between January 25 to March 9, 2011, 9 drill holes were completed for a total of 1,566 m at the Boundary Zone. Drill holes, including BZ11-38 to -46 (and BZ11-35A), were designed to fill in gaps between previous drill holes and to expand the zone along dip and strike. It was anticipated that this drilling would generate a resource at Boundary. As previously provided, on December 1, 2011 a NI43-101F1 Technical Report for Bidgood South and Boundary Zones was signed and submitted.

Mud Lake Zone

From January 12 to April 2, 2011 and June 26 to July 25, 2011, fourteen drill holes were completed at Mud Lake and Bidgood #1 Mine totaling 5,125.35 m. Drill holes ML11-01 to -13 (including ML11-11A) were designed to test King Quartz Stockwork ("KQS") and possible Kirkland Main Break trend as discovered in 2008 with drill hole LB08-35, associated structures on the Mud Lake 'south arm', Bidgood #1 Mine vein systems and deep IP anomalies as provided in a February 2010 survey of the KQS Zone.

Diamond Drill Company

In 2011, Cabo Drilling (Ontario) Corp. performed all of the diamond drill activities at Bidgood, Boundary and at Mud Lake.

8.0 SAMPLING METHOD AND APPROACH

8.1 GENERAL PROTOCOL

- All diamond drill core logging and sampling activities were supervised by Project Geologists (McCormack[4], Sutton[5], Zalnieriunas[6], Greaves[7], and Wade[8]).
- Drill core sample intervals are selected on a geological basis and most typically varied between 0.5 and 1.5 m (1.6 to 4.9 ft.) in length and very rarely are less than or greater than these values.
- Drill core sample demarcation is conducted by the Geologist while core logging. Core samples are entered into a digital database, (Excel file) whereby the spreadsheet format includes the drill hole number, "from"–"to" in metre interval, sample width in metres, sample ticket number, and sample description. Assay results received from assay labs are inserted into the database according to the corresponding sample number.
- Electronic certificate files received from assay laboratories are compared to hard copy, signed certificates for possible discrepancies.
- In regards to sampling Quality Assurance/Quality Control, field gold standards and field blanks are entered into the core sample flow, at approximately every 25 metres and monitored for any abnormal gold concentrations or trends. Selected pulp and rejects returned from Polymet are submitted to Swastika Laboratories[9] ("Swastika") and AGAT Laboratories[10] ("AGAT") which are independent of Polymet, as a check on Polymet ½ core assays. Selected ½ core samples are also ¼ sawn and submitted to Polymet as a comparison to the original ½ core assay.

Marking Core Samples

- Geologists identify the beginning and end of samples directly on the core with a line perpendicular to the core and an arrow identifying direction of the sample. Samples are demarcated using a china marker or a grease pencil. A line is also traced along the long axis of the core defining the cutting line, which the core cutter will follow, to obtain a representative sample.
- A sample tag is placed at the beginning of the sample and is stapled on the core box at this location as record and for verification purposes.
- Each core tray is labeled according to sequential core tray number, drill hole number and representative depth interval.

8.2 SAMPLE HANDLING, PREPARATION, ANALYSIS AND SECURITY

Drill core, secured in enclosed core trays, is collected at the drill site by Queenston personnel and transported directly to the core logging facility at the Toburn Mine Site[11]. Logging facilities are secured by lock with only Queenston personnel and the building owner possessing keys. Only authorized personnel are allowed in the logging and core cutting facilities. Once inside the core logging facilities tray lids are removed, core is measured, tray tags are applied and trays are racked in preparation for logging. Core remains inside the facility for the entire sample processing flow from logging to core cutting to sample bagging, in preparation for shipment.

Geologists log the core and demarcate samples as previously provided. Sample tickets, obtained from Polymet are utilized at all times for identifying samples. Each sample ticket has a unique series and numerical identity to mark individual core samples as identified by the geologist. Core cutting technicians place ½ core samples with the corresponding sample ticket into 10"x15"x.006 mil clear plastic bags and secure each bag with a cable tie. The other half of the sample ticket is stapled to the core tray at the beginning of the sample. Eight to twelve individual sample bags are placed into rice bags and secured with a security tag having its own identifying number. For shipment, the rice bag is marked with the Receiving Lab address and sequential rice bag number of the total number of rice bags to be shipped. A Chain of Custody form is provided in the first rice bag of the shipment outlining the number of rice bags in the shipment, sample number series in each rice bag and total number of samples. The security tag column on the form is intentionally left blank and is 'filled-in' by the receiving Lab to return by fax to Queenston with the correct security tag number. This ensures that the security tag is not breached during shipment and that the samples are secure.

After core is cut, ½ core remaining in core trays are transported for storage at Queenston's Lebel or Upper Canada sites. Core trays are stacked and strapped to pallets or placed in core racks.

Assay Methodology – Polymet

Individual core samples normally weigh 0.5 to 2.5 kg in weight and are dried before crushing. The entire sample is crushed in a steel jaw crusher with 90% to -8 mesh, then split into 200 to 450 g samples using a Riffle Splitter. This portion is pulverized to 90% -150 mesh using a ring pulverizer. Brushing and compressed air cleaning is performed between each sample to prevent cross-contamination. A silica wash is used only after processing samples that are noted or marked containing visible gold or if an inspection proves any build-up on the rings or bowl. At every 15th sample, the ground wash material from the pulverizer is forwarded in sequence for analysis by fire assay. The data from the washes must be consistently <0.03 gAu/t to support

[11] Toburn Mine Site. Managed by the Toburn Operating Authority and owned by The Corporation of the Town of Kirkland Lake. Government Road East, Kirkland Lake, ON.

the effectiveness of the cleaning protocol. All samples are submitted for fire assay with pulps and rejects returning to Queenston.

Gold is determined by fire assay of a 14.58 g fire assay charge. The analysis begins with a fusion of flux mixture and sample added to a crucible placed in an assay furnace leading to a resultant lead button. The lead button is melted into a cupel with the remaining gold bead ready for weighing. For core samples with gold assays exceeding 1 gAu/t, a check assay is performed whereby a second cut off of the reject is taken, pulverized for a second pulp for an additional, separate fire assay.

Polymet performs its own quality assurance and control whereby internal blanks and standards are inserted every 48 samples. Polymet is ISO9001:2000 registered.

Swastika and AGAT have similar assay methodologies with fire assay and AAS[12] or ICP-OES[13] finish.

Data Entry

Assays are reported by Polymet, Swastika and AGAT, by both electronic certificate and original, signed hard copy certificate. Queenston personnel compare and verify electronic data to hard copy data. Assay database input is performed and/or reviewed by Sutton, McCormack and Patti Rozich[14] ("Rozich") to avoid the possibility of data input error.

Data Verification

Field Blank

Crushed cement blocks, placed in sample bags with sample tickets, are inserted into the sample core flow usually following a sample having suspected gold mineralization in order to detect possible contamination to surrounding samples. Of the 20,700 samples assayed for the Bidgood Project in 2010-11, 941 field blanks were inserted or 4.5% of total samples assayed. With respect to field blank assays, any assay over 0.03 gAu/t were reviewed. If it were determined that possible contamination occurred, sample rejects surrounding the abnormal blank assay were either re-assayed or core samples were ¼ sawn and re-submitted for assay.

Field Standard

[12] AAS. Atomic Absorption Spectroscopy.
[13] ICP-OES. Inductively Coupled Plasma-Optical Emission Spectroscopy.
[14] Patti Rozich. Land and Project Administrator, Queenston Mining Inc. 36 Prospect Avenue. Kirkland Lake, ON P2N 2V4.

Two certified field standards were inserted at approximately every 25 metre intervals using RockLabs[15] Si54[16], OxL63[17] and OxL93[18] For the Bidgood Project 845 field standards were inserted or 4.1% of the 20,700 samples assayed. Where field standard assays went beyond three standard deviations from the average, standards were reviewed and re-assaying of surrounding core samples was undertaken or review of referee analysis of pulp and rejects would be performed.

¼ Sawn Core

Selected ½ core samples were identified with an additional sample ticket for sawing ¼ of the ½ core as a check for gold variability and check on the ½ core assay. In regards to both projects the following ¼ samples were taken;

103 core samples were ¼ sawn or 0.5% of the total number of core assays.

Even though variance occurs between ½ and ¼ core assays, ¼ core assisted in evaluating core where contamination was suspected, when visible gold was observed while logging or where a high grade assay was returned.

Referee Samples (Pulps and Rejects)

Pulp and reject samples from the original ½ core analysis (as performed by Polymet Labs) were submitted to Swastika and AGAT laboratories for referee analysis. Of the 20,700 core samples assayed, 812 pulps and 963 rejects were submitted for referee analysis representing 3.9% and 4.6% of the total core assays respectively.

Referee assays of pulp and rejects compared relatively well with Polymet assays. Referee assays were also used as a check on core assays surrounding abnormal field blank or standard assays, high grade assays and from samples where results were suspect.

Screened Metallic Fire Assay

Five samples from Boundary Zone and one sample from Bidgood were submitted for screened metallic fire assay at AGAT and Swastika respectively. Resultant screened metallic assay ranged from +/- 0.6% to 20% when compared to Polymet ½ core fire assays.

2010-11 Boundary Zone Highlights (Figure 21)

9.3 BIDGOOD SOUTH ZONE AND BOUNDARY MINERAL RESOURCE ESTIMATE

On October 17, 2011 Queenston announced a NI 43-101 resource for the Bidgood Project, representing the first resource calculated since the closure of the Bidgood Mine in 1951.
The resource incorporated 107 surface diamond drill holes (13,233 m) from the 2010 -11 drill programs and 23 historic holes (3,632 m) completed by previous operators. Of the historic veins developed on the Bidgood Mine property, the resource consists of the #1 & #2 veins & part of #20 vein & part of Main Break and represents 17% of Bidgood footprint in resource (to -150m).

As a result of the 2010-11 drill program, new gold-veins have been discovered within and to the south and north of the South and North Zones.

The resource for Bidgood and Boundary (In-Pit and Underground Mineral Resource Estimate) as provided by P&E Mining Consultants Inc.[19], December 1, 2011 is as follows;

BIDGOOD AND BOUNDARY IN-PIT AND UNDERGROUND MINERAL RESOURCE ESTIMATE

Capped	Indicated			Inferred		
Cut-Off Au g/t	Tonnes	Au (g/t)	Au (oz)	Tonnes	Au (g/t)	Au (oz)
Pit 0.42 g/t	1,438,000	1.66	76,000	242,000	1.68	13,000
UG Below Pit 2.3 g/t	26,000	3.28	3,000	76,000	3.09	8,000
Total	**1,464,000**	**1.69**	**79,000**	**318,000**	**2.02**	**21,000**

Uncapped Sensitivity	Indicated			Inferred		
Cut-Off Au g/t	Tonnes	Au (g/t)	Au (oz)	Tonnes	Au (g/t)	Au (oz)
Pit 0.42 g/t	1,447,000	2.47	115,000	246,000	2.88	23,000
UG Below Pit 2.3 g/t	43,000	7.05	10,000	136,000	7.52	33,000
Total	**1,490,000**	**2.60**	**125,000**	**382,000**	**4.53**	**56,000**

1) Mineral resources which are not mineral reserves do not have demonstrated economic viability. The estimate of mineral resources may be materially affected by environmental, permitting, legal, title, taxation, socio-political, marketing, or other relevant issues, although the Company is not aware of any such issues.

[19] P&E Mining Consultants Inc. "Technical Report and Resource Estimate for the Lebel Gold Deposit of the Kirkland Lake Gold Project, Lebel Township, Kirkland Lake, North-Eastern Ontario, Canada" NI 43-101F1 Technical Report No 209. Effective Date: September 15, 2011, Signing Date: December 1, 2011.

(2) The quantity and grade of reported Inferred resources in this estimation are uncertain in nature and there has been insufficient exploration to define these Inferred resources as an Indicated or Measured mineral resource and it is uncertain if further exploration will result in upgrading them to an Indicated or Measured mineral resource category.
(3) The mineral resources in Table 1.1 were estimated using the Canadian Institute of Mining, Metallurgy and Petroleum (CIM), CIM Standards on Mineral Resources and Reserves, Definitions and Guidelines prepared by the CIM Standing Committee on Reserve Definitions and adopted by CIM Council.
(4) Grade capping of 7 g/t was utilized on raw assays for Boundary, 15 g/t for 20 Vein, and 22.5 g/t for the rest of Bidgood.
(5) A bulk density of 2.87 t/m³ was used for all tonnage calculations.
(6) A gold price of US$1,300/oz and an exchange rate of US$0.98 US=C$1.00 was utilized in the Au cut-off grade calculations of 0.42 g/t for open pit and 2.3 g/t for underground. Open pit mining costs were assumed at C$3.00/t for mineralized material, C$2.50/t for waste rock and C$1.75/t for overburden, while underground mining costs were assumed at C$75/t, with process costs of C$12/t and G&A of C$5/t. Process recovery was assumed at 95%.
(7) Values in the table may differ due to rounding.
(8) The area of influence of the indicated category is 20 m up/down dip, 15 m along strike, and 10 m across dip from a known sample point (drill holes), with a minimum 2 drill holes and max of 20 samples; other blocks within the hard-wireframe/ constrain are coded as inferred.
(9) The open pit resource is reported within a Whittle optimized pit shell.

9.4 2010-11 BIDGOOD NORTH ZONE

TABLE

10.0 RECOMMENDATIONS

Bidgood Mineral Resource

The South Zone and Boundary mineral resource warrant continued diamond drilling for delineation (to upgrade tonnes from inferred to indicated category) and for expansion. Historic veins #1, #2, #6, #11, #10, #15, #20 will be targeted to expand the open-pit resource to the north, north-east and west. New veins south of the South Zone will be targeted to expand the open pit resource south.

Drilling is recommended for Boundary Zone for delineation and expansion to the south-west and east.

North Zone and Deep North

North Zone veining and new veining warrant continued drilling to understand continuity and dimensions. Drilling will concentrate on historic areas #1, #2 and # 3 veins as well as new veins discovered to the north of the veins.

Given initial results from drill holes BG11-87 and BG11-163 and historic intersections from underground drilling from the 2025 Level of the Bidgood #2 Mine, further deep testing (below the 2025L) is warranted.

The 2012 budget for South and North Zone drilling is provided in the following table;

RECOMMENDED NORTH & SOUTH ZONE TARGET DRILLING

ZONE	# HOLES	AVE. DEPTH	METRES	COST
NEW NORTH	15	100	1500	$135,000
1-2-3 VEINS	21	80	1680	$151,200
#11 VEIN	29	130	3770	$339,300
#6 VEIN	57	166	9480	$853,200
#20 VEIN	54	174	9390	$845,100
NEW HG	18	80	1440	$129,600
MAIN EAST, WEST	12	100	1200	$108,000
M-H WEST	8	80	640	$57,600
M-H NEW SOUTH	16	100	1600	$144,000
TOTAL	**230**		**30,700**	**$2,763,000**

Exploration Targets

The following table provides a budget for zones of interest located on the Lebel Property.

RECOMMENDED - SHALLOW DRILLING, OTHER TARGETS

ZONE	# HOLES	AVE. DEPTH	METRES	COST
OLD STOPE	2	100	200	$18,000
RED'S	3	120	360	$32,400
83-27 DIORITE	3	200	600	$54,000
BOUNDARY	10	101	1010	$90,900
BLUE WEST	10	200	2000	$180,000
BLUE EAST	8	160	1280	$115,200
MAIN @MUD	4	150	600	$54,000
CLIFF	4	100	400	$36,000
NEW POR (08-48)+SHAFT	4	150	600	$54,000
MAIN@ 08-42	2	100	200	$18,000
83-25, MUD SOUTH	4	200	800	$72,000
TOTAL	**54**		**8,050**	**$724,500**

STATEMENT OF QUALIFICATIONS - MCCORMACK

I, Daniel J. McCormack, of King Kirkland, in the PROVINCE of ONTARIO, hereby certify:

I am a geologist and currently a consultant to Queenston Mining Inc.

Up to May 2010, during a portion of the 2010-11 Lebel diamond drill program, I was a director and an officer of Vault Minerals Inc. with the position of Vice President operating out of Vault's Kirkland Lake Office. After May 2010, I was retained as a geology consultant to Queenston Mining Inc.

I graduated from the University of Waterloo, H.BES in 1984.

I have practiced as an exploration or mine geologist from 1984 to 1993 and from 2001 to present with experience that has included design, implementation & management of grassroots to advanced exploration programs and as part of mine production operations in Canada.

I am currently registered as a professional geoscientist (membership number 1321) with the Association of Professional Geoscientists of Ontario (APGO).

This report is based on a study of all information made available to me, both published and unpublished, and on information collected by me and Michael Sutton, P.Geo during the period January 2010 to December 2011, with assays collected in 2012.

Dated in Kirkland Lake this twenty-second day of October, 2012.

Daniel J. McCormack, P.Geo. 1321

STATEMENT OF QUALIFICATIONS - SUTTON

I, Michael W. Sutton, of the TOWN of KIRKLAND LAKE, in the PROVINCE of ONTARIO, hereby certify:

I am a geologist and currently a consultant to Queenston Mining Inc. and during a portion of the 2010-11 Lebel drill program (January to May 2010) held the position of Vice President Exploration for Vault Minerals Inc., operating out of Vault's Kirkland Lake Office.

I graduated from the University of Toronto, H.BSC in 1986.

I have practiced as an exploration or mine geologist from 1984 to present with experience that has included surface and underground grass-roots to advanced exploration programs and as part of mine production operations in Canada. I have extensive experience at Macassa mine, having been the Chief Geologist.

I am currently registered as a professional geoscientist (membership number 0594) with the Association of Professional Geoscientists of Ontario (APGO).

This report is based on a study of all information made available to me, both published and unpublished, and on information collected in the field by myself and Dan McCormack.

Dated in Kirkland Lake this twenty-second day of October, 2012.

Hole_ID	From	To	Lith 1	Lith 2	Lithology Name	Colour1	Colour2	Grain Size 1	Grain Size 2	Text	Text	Description
BG10-01	0.00	21.50			Casing							21 to 21.5m boulders
BG10-01	21.50	39.46			Crystal Tuff	med green	dark green	fine	aph			as with units at start of holes for BG10-92, -94 and -101, non-magnetic; weak to strong carb alt'n; 5-10% pale white carb + calcite vn's predominantly at low angles; weak fol'n fabric; rounded -absorbed appearance irregular xeno's with fine to med pale beige-light brown feld pheno's - almost appears like a fine grained sed - or Conglomerate?; occasional appearance of iron black, euhedral, hard sometimes cubic x-stals - possible spinel? non-magnetic; **Shear - Flt Zone starts from 33.5 to 40.4 m with strong mud flt gouge at 39.35 to 39.46 m, shear is ductile non-penetrative frac fabric perv chl + ser mottled texture with feldspar pheno's, becomes perv carb+oxy'd hem? orange colouration from 37.9 to 39.1m with strong py + carb in frac's from 37.9 to 38.2m and 38.5 to 39m on HW of Flt - 20 Vein Extension? should be on FW side of Flt;** mud flt at contact with diorite at 45 deg TCA
BG10-01	39.46	40.63			Diorite	dk green		aph	fine			non-magnetic; 10% leuc flecs; strong ductile shear at 45 to 60 deg TCA immediately after Mud Gouge Flt; strong perv carb + chl; 5% discontinuous late carb+ank vn's; strong shear zone ends at 40.1m; sharp irregular contact at 40.63
BG10-01	40.63	41.45			Syenite	dk grey		aph				mafic syenite; strng perv carb; non-magnetic; broen core lower contact
BG10-01	41.45	53.50			Diorite	dk green		aph	fine			predominantly non-magnetic' strng perv carb alt'n + minor chl; 5-15% leuc flecs; 5-15% late qtz+carb and later white carb + calcite in frac's; *10cm wide carb + py vn at 46.8 to 46.9m;* strong cpy occurrences with occasional spec hem in late carb+calcite 0.25 to 4cm wide vnlets from 46.6 to 51.5m
BG10-01	53.50	54.80			Feldspar Porphyry	red brown	grey brown	aph	fine			possible FP; non-magnetic; perv carb; strong brittle frac'ing with carb+chl; 3-5% py diss and in frac's; sharp contacts with diorite
BG10-01	54.80	58.30			Diorite	dk green	med green	aph	fine			magnetic; strng perv carb; 10% late white carb vn'ing; negl py
BG10-01	58.30	61.15			Diorite Breccia	dk green	med green	aph	coarse			non-magnetic; aph matrix with irregular subrounded to subangular clasts - roof pendant appearance - clasts are moderately hard to soft and dk green to light green in colour -; unit does not have strng perv carb like previous unit, carb confined to late frac'ing ~5%; some calcite + carb vn'ing from 59.7 to 60.2m with 1-3% py; ***at 61.15 to 61.3 m Diorite Breccia + Diorite contact an 80% py carb vn at 50 deg TCA***
BG10-01	61.15	62.80			Diorite	med green		aph				non magnetic; negl py; **at 62.64 to 62.8m Diorite-Diorite Breccia contact a 16 cm carb+ank vn with 2mm to 7mm wide frac's having py + magnetite+ cpy, overall py at 5-7%**
BG10-01	62.80	69.00			Diorite Breccia	dk green	med green	aph	coarse			as with 58.3 to 61.15m; 15-20% pink - white late carb+calcite vn'ing with spec hem + py
BG10-01	69.00	73.93			Diorite							**as with previous Diorite Breccia - Diorite contacts 71.9m to 73.2m 10-15% py in carb + qtz+ ank vn'ing**
BG10-01	73.93	81.26			Syenite	dk green	dk grey brown	aph	fine			both upper & lower contacts with Diorite are sharp and > 65 deg TCA; non-magnetic; mod to strong perv carb alt'n and in mod density brittle frac's; 5% late white carb vn'ing
BG10-01	81.26	83.60			Diorite	dk green		aph				good shear from 82.6 to 83.5m; 82.6 to 82.8m FP
BG10-01	83.60	90.56			Feldspar Porphyry	dk mauve brown		fine	med			upper contacts at 45 to 50 deg TCA with chl+talc; bimodal; non-magnetic; strng perv carb; tabular feld pheno's show fabric fol'n 55 to 65 deg TCA; diorite, magnetic fro 83.9 to 84.71m; lower contact sharp, definitive at 85 deg TCA
BG10-01	90.56	136.50			Diorite	dk green		fine				strngly magnetic; strng to mod perv carb; mottled colour given by spotty epi alt'n; 5-10% late white carb vn'ing; occasional 100% magnetite stringers; weaker perv carb from 123m to 131m; variable sections within the diorite that precipitated more magnetite than others - some sections are non-magnetic; at 135.6m ser alt'n increases towards MH Zone, perv carb diminishes after 136m; lower contact with porphyry is sharp at 30 deg TCA, however muted by ser alt'n
BG10-01	136.50	149.70			Feldspar Porphyry	grey brown	red-brown	fine	med			non-magnetic unit; **immediately at contact MH Zones start 136.5 to 141.7m, 142.25 to 143.3m, 145.5 to 147m, Ito lesser extent 148.3 to 147.7m and continues into diorite with small intervals, MH Zone typified by strong fg & lesser mg py sometimes up to 25%, perv grey-white-bk blue hue sil ~25 to 55%, <2% late white qtz+ank stringers, py sometimes in frac's, fol'n fabric at 45 to 60 deg TCA but hard to discern, obliterated by sil alt'n, some sections have brick red oxy'd hem alt'n;** diorite unit from 140.7 to 140.9m 1-2% py
BG10-01	149.70	158.66			Diorite	dk green	grey green	aph	fine			magnetic except where perv sil alt'n; **MH Zones - intervals of brittle frac'ing with sil alt'n + hem oxy'd + py mineralization at 150.06 to 150.3m, 152.6 to 156.2, and 157.4 to 158.3m;** unit has perv carb alt'n; sharp lower contact at 65 to 75 deg TCA
BG10-01	158.66	171.00			Feldspar Porphyry	grey	grey green	aph	med			non-magnetic; bimodal; strng perv carb alt'n; <1% diss py in hairline frac's and in matrix; end of hole intersected wood - possible gangway in drift or shaft? ; FP is not mineralized or altered prior to wood intercept- EOH
BG10-02	0.00	18.70			Casing							

BG10-02	18.70	39.70			Crystal Tuff	med green	dark green	fine	aph			possible Cngl or Diorite Breccia; non-magnetic; perv carb + weaker chl alt'n + mild epi alt'n; occasional Late white-grey carb vn'ing <5% at various angles TCA; euhedral + cluster anhedral blebs of py in matrix or along frac's at 1%
BG10-02	39.70	43.50			Diorite	med green	med grey-green	aph	fine			non-magnetic; feld pheno's give mottled appearance; <5% late white carb vn'ing; lower contact at 20 deg TCA
BG10-02	43.50	44.55			Crystal Tuff	med green	dark green	fine	aph			as with 18.70 to 39.7m; lower gradational contact looks like a crackled version of diorite which supports calling this unit a diorite breccia
BG10-02	44.55	57.20			Diorite	med green	grey green	fine	aph			strngly magnetic where unaltered; strng perv carb alt'n; *Shear Zone starts at 47m to 63.7m with a 3 cm wide mud gouge Flt at 57.25m, some shear sections with increased carb+ carb+qtz+ank vn'ing, minor ser + minor py and cpy,* 55.7 to 56.05m syenite dyke; lower contact of diorite in contact with syenite at mud gouge flt at 20 deg TCA
BG10-02	57.20	63.00			Syenite	dk grey	brown grey	aph	fine			non-magnetic; mod perv carb alt'n; augites are chl; sections show fol'n fabric sometimes shear planes with qtz+ank+carb vn'ing + minor py, splash of cpy, mod section from 61.5 to 62m; strong alteration 30 cm within mud flt but negl py; diorite from 62.1 to 62.3m; lower contact sharp & definitive at 60 deg TCA
BG10-02	63.00	75.30			Diorite	dk green	light green	aph	fine			sections are magnetic and non magnetic; weak to strong perv carb; intervals with strong perv pale pink brown sil? alt'n with strong qtz+ank+carb vn'ing at 71.26 to 72.7m, 73.75 to 74.1m - alteration fronts have sharp definitive & gradational contacts, py is minimal confined to frac's; irregular contact with FP
BG10-02	75.30	77.80			Feldspar Porphyry	pale brown	pale pink brown	aph	med			non-magnetic; weak bimodal feld phen's; strong fol'n fabric; 15-25% late qtz+ank+carb vn'ing; 75.45 to 75.8m sheared possible diorite with 30% late pale white qtz+ank+carb hydrothermal bx vn'ing fg py in hairline frac's in carb section; 77.1 to 77.4m strong grey perv carb alt'n with 8-10% fg py; irregular lower contact
BG10-02	77.80	90.57			Diorite	dk green	med green	aph	fine			non-magnetic where altered; otherwise weak to strongly magnetic 78.5 to 79.05m an opaque pale grey-white 95% qtz+ank+carb vn with chl frac's & negl py followed by and up to 79.7m an sil perv pink brown alt'n front with 35-40% late qtz+ank and grey qtz negl py; after 79.7m unit strongly magnetic 5-15% late grey carb vn'ing + perv carb alt'n; lower contact with FP sharp and definitive at 30 deg TCA; lower contact at 35 deg TCA
BG10-02	90.57	96.87			Feldspar Porphyry	grey red brown		aph	coarse			non-magnetic, bimodal; perv carb alt'n; 70 deg TCA shear section between 94.4 to 94.6m with ser+chl alt'n + two 1cm qtz vn's; negl mineralization; feld pheno's show fabric fol'n; lower contact irregular

Certificate of Analysis

Queenston Mining Inc.
Lebel Project

We certify that the assay results in the following Certificates are factual and true.

Certificate #'s 11559, 11560, 11561, 11562, 11563, 11564, 11565, 11566, 11567, 11568, 11569, 11570, 11571, 11572, 11573, & 11574

Certified by: _____
Assayer

Certified by: _____
President/Manager

Date: October 24, 2011

Disclaimer: The results included on this report relate only to the items tested. The Certificate of Analysis should not be reproduced except in full, without the written approval of the laboratory.
